dark blue berry. On opening this berry I find only a hard kernel inside. I want to sow the seed, and would like to know if this kernel is to be sown whole, or are there seeds inside it? I have only about half a dozen and have not broken any yet, but they seem quite solid and not as if they contained any seed. I believe this is the only place in this part of the world where this Tropscolum has flowered. I have tried it in various aspects, and the only place it has shown a flower is against a bow window facing the east. It flowers abundantly on the west coast of Scotland, and it is strange it has not hitherto flowered in a western aspect in Ireland. However, the N.W. gales from the Atlantic are our greatest enemy here.—AMATEUR, Sligo.

I HAVE never grown this Troppeolum from seed. We generally succeed in getting more plants than we require growing up from the roots; they are springing up in all directions, even in the hard gravel walks. I think it would grow freely enough from seed if sown in some light compost with a little bottom heat. The seed is covered with a pretty dark blue skin, and should be sown as it is gathered. This beautiful climber delights in a humid atmosphere, hence the reason why we succeed in growing it so well in this locality. In the south I would recommend growing it on a wall with a north aspect or in some shady part of the shrubbery or plantation. I have seen it very pretty growing up the limbs of bare shrubs.—

JAMES DICKSON, Arkleton, N.B.

WOOD LILIES (TRILLIUM).

THESE beautiful hardy plants have received their common appellation because of their love of shady places, and the fact that in their native homes they reveal a great preference for woody or shady spots, growing amongst long grass, low shrubs, and other places where they receive shade and plenty of moisture. Their generic name is also very significant, as it moisture. means triple, in allusion to the foliar and floral organs. although the arrangement of the latter is one of the primary distinguishing marks, not only of the family to which the Wood Lilles belong, but also of the great division of plants in which the family is included. But in the genus Trillium we have the true calycine and coralline parts of the flower represented, which is by no means very common in monocotyledons—i.e., as far as the colour distinguishes them; for while the three inner divisions of the permuth are otherwise coloured than green, the outer three are green. But we have they are exceedingly attractive, especially T. grandiforum.

They succeed well if planted in damp shady situations, which is a fact that should favour their much-extended cultivation. is a fact that should revour medi-exemics constrained frowing with Ferns, in association with Cypripedium spectable and numerous other plants, they add another charm to that part of the outdoor garden. The soil they best thrive in is peat, loam, leaf soil, and sand; but if such is not to hand that need one be an obstacle in the way of cultivating them, as they do well in ordinary garden soil, but do not like heavy soils. They are very suitable for growing in pots, more especially the one mentioned above, which is a charming plant for pot culture and the decoration of the conservatory or cool greenhouse. It forces well, and so it may be had in bloom very early in the season.

There have been about seventeen species of Wood Lilies described, although all have not been introduced. Some of those which have been introduced are now lost to cultivation in this country, but as that part of America in which they are found is now well explored for hardy bulbous and other plants it is probable we may soon have them again. Those enumerated below are most likely to be easily obtained, and are the

T. atropurpurcum (T. erectum).—Widely distributed over North America, growing about 6 or 9 inches high. Flowers deep brownish purple, slightly drooping, expanding in April

deep brownish purple, signily drooping, expanding in April and May. Introduced 1759.

T. erythrocarpum (T. pictum).—A beautiful species, also widely distributed over North America, producing white flowers curiously splashed with reddish purple, rendering it at once distinct. Flowers in May and June. Introduced 1811.

T. grandiforum.—This is the most charming species known to the control of the

to us; it grows from 9 to 18 inches high, producing large Lily-like white flowers, which last a considerable time. Flowers in June and July. Introduced 1799.

T. petiolatum.—This is a pretty little species growing about 9 inches high, producing large reddish purple flowers, quite sessile in the rather large cordate leaves. Flowers in April and May. Introduced 1811.-T.

GRAND DUKE PLUM.

SINCE this Plum was referred to on pp. 380 and 382 we have received fruits of it, one of which is represented in the annexed engraving. The fruit is oval, with a short neck and a well-defined suture, which is deep at the stalk, and frequently so at the apex, where it is sometimes higher on one side than the other. Skin dark, almost a blackish purple, but reddish where shaded, and covered with blue bloom. Stalk 1 to 14 inch long, very siender, and inserted in a round narrow cavity. Flesh greenish yellow, adhering closely to the stone, very brisk, with a sweet and rich flavour when fully ripe. Stone with a very shallow and narrow changel, like a thread.

Leaves large and glossy. Young shoots smooth.

To Mr. Rivers of Sawbridgeworth we are indebted for this welcome addition to our late l'iums. As has been previously

Fig. 42.—Grand Duke Phun.

mentioned it is a seedling from Autumn Compôte, and promises to prove a valuable acquisition. Besides being decidedly late (the fruit figured was gathered in November) it is of excellent quality, and the tree is one of the best growers of all Plums. This feature is strikingly displayed in Mr. Bunyard's nursery at Maidstone, where all the best varieties are cultivated and excellently grown; but the rows of Grand Duke are the finest of all. In the Sawbridgeworth Nursery are many handsome pyramids in a bearing state. For this form of culture it is clearly well adapted. It will make a fine wall Plum, and of a wall it is worthy, and will form excellent espatiers. Grand Duke is likely to prove a Plum of real usefulness, and in all probability it will be largely grown.

RIVINA HUMILIS.

AN old plant, by no means rare, and as generally seen it is not deserving much attention, but young dwarf plants when well grown are not surpassed by any other berried plants as an effective table ornament. Its foliage is comparatively small, but sufficient to set off the depending racemes of brilliant T. pendulum.—A very distinct species, producing greenish coral bead-like berries so profusely produced, the plants exwhite flowers of a good size in April and May. Introduced 1805. hibiting at the same time racemes of white flowers, and it may be had in season throughout the year by having plants in

different stages of development.

The best plants are obtained from seeds. The seeds germinate in a few days if sown in light soil and placed in gentle heat, and when the seedlings are large enough pot them off singly in small pots, keeping them near to the glass, and shifting into larger pots when necessary. Pots 4 to 6 inches in diameter are sufficiently large. It must be kept as near the glass as possible, so as to render it sturdy, for if grown at a distance from the glass the growth is weak and attenuated. It succeeds in light turfy loam. Plants raised from seed sown in April and grown on through the summer in pits or frames will be in berry by early autumn, and if afforded a light airy position in a cool stove or intermediate house they will be useful for the greater part of the dull season. It is injured by a high temperature, not only being drawn, but the berries are not so enduring. -G. ABBEY.

FRUIT SHOW AT THE SOUTHPORT WINTER

THE second annual Fruit Show was held in the conservatory on the 13th and 14th inst. It was thought by many that the Exhibition this year owing to the cold season would be only a poor one, but it proved upon the whole very meritorious, numerous splendid dishes being exhibited. All classes were open, hence the

firm competition.

For twelve dishes of fruit, Pines excluded, Mr. Upjohn, gardener to the Earl of Ellesmere, and Mr. Hannagan, gardener to R. C. Naylor, Esq., were equal first. The former collection contained fine examples of Gros Colman and Black Hamburgh Grapes; Marie nne examples of Gros Colman and Black Hamburgh Grapes; Marie Louise, Doyenné Boussoch, and Doyenne du Comice Pears, splendid in size and colour; Maréchal de Cour was also very fine. Apples were Fair Maid, Court of Wick, and Parkell Seedling, and the collection included a good Queen Emma Melon. The latter staged good dishes of Gros Colman, Black Hamburgh, Muscat of Alexandria, and Madresfield Court Grapes, with splendid examples of Beurré Clairgeau, Maréchal de Cour, Beurré Diel, and Flemis Results Pears : Ambles King of the Plannin and Beauty Pears; Apples, King of the Pippins, Ribston Pippin, and

Beauty Pears; Apples, King of the Pippins, Ribston Pippin, and Golden Reinette, with a fine well-finished fruit of Conqueror of Europe Melon. In the collection of six varieties Mr. Hannagan was again first; Mr. Hurst, gardener to B. Bowering, Eaq., was a close second; and Mr. Hatton, gardener to S. Swire, Esq., third. In the class for six varieties of dessert Apples many splendid dishes were staged. First honours were deservedly secured by Mr. Gardener, gardener to E. Phillips Shirley, Esq., with highly coloured fruit of Lord Duncan, Wyken Pippin, Fearn's Pippin, Adams' Pearmain, Mannington Pearmain, and Ribston Pippin. Mr. Lowndes, gardener to S. S. Parker Reg. was second and Mr. Adams' Pearmain, Mannington Pearmain, and Ribston Pippin. Mr. Lowndes, gardener to S. S. Parker, Esq., was second, and Mr. Whitfield, gardener to T. Cross, Bsq., third. In the class for three dishes of dessert Apples, distinct varieties, Mr. Lowndes was first with Ribston Pippin, King of the Pippins, and Blenheim Pippin. For a single dish of ripe fruit Mr. Whitfield was first with very good Ribstons. For six dishes of kitchen Apples there was very keen competition. Mr. Hannagan was an easy first with fine examples of Warner's King, Emperor Alexander, Greenup's Pippin, Alfriston, Lord Suffield, and Mère de Ménage. Mr. Gardener was a good second with Golden Noble. Cox's Pomona. New Hawa good second with Golden Noble, Cox's Pomona, New Hawthornden, Warner's King, Yorkshire Greening, and Winter Nonesuch; Mr. Whitfield being a close third. In the class for three dishes Mr. Whitfield was first with American Mammoth, Nelson's Glory, and Lord Suffield. For the best single dish Mr. Gardener

was first with Warner's King.
In the class for six varieties of dessert Pears, Mr. Hannagan won the premier prize with wonderful specimens of Beurré Clair-geau, Duchesse d'Angoulème, Doyenné du Comice, Beurré Diei, Marie Louise, and Maréchal de Cour. Mr. Gardener was a good second, and Mr. Lowndes third. For the best dish of ripe fruit Mr.

John Smith was first with Marie Louise.

John Smith was first with Marie Louise.

The Grape classes were well filled. In the class for two bunches of Muscata Mr. Hatton was first with two splendid well-finished bunches, Mr. Hannagan second, and Mr. Hall, gardener to J. Whittaker, Esq., third. For two bunches of Black Hamburgh the first prize went to Mr. Halewood, Hesketh Park, Southport; second to Mr. J. Phythian, gardener to Mrs. Robinson; and third to Mr. Helder. For one bunch of Muscat Mr. Hurst was first with to Mr. Holder. For one bunch of Muscat Mr. Hurst was first with to Mr. Holder. For one bunch of Muscat Mr. Hurst was first with a very fine well-finished bunch weighing 5 lbs. For one bunch of Black Hamburgh Mr. Holder was first. In the class for one bunch of any variety Mr. Upjohn was placed first with that very coarse variety called Meredith's Child of Hale. In the class for one bunch, any other Black variety than Hamburgh, first Mr. Upjohn with a grand example of Gros Colman; second Mr. Jamieson, gardener to the Earl of Crawford, with Black Alicante.

In the Pine Apple class there were some noble examples staged. The first prize went to Mr. Hatton for a splendid fruit of Smooth

The first prize went to Mr. Hatton for a splendid fruit of Smooth Cayenne; second to Mr. Jamieson for the same variety; and third to Mr. Upjohn for a fine Prince Arthur. To Mr. Campbell, the Curator, we tender our congratulations for

the able manner in which he carried out the Exhibition arrangements, unaided as he was by any Committee. The Judges were Mr. Shaw of Bowden, Manchester; and Mr. Mackellar, Abney Hall, Manchester.

NOTES AND GLEANINGS.

THE following are the arrangements decided upon for the Meetings, Shows, &c., of the ROYAL HORTICULTURAL SOCIETY for the year 1880 :- Fruit and Floral Committees Tuesdays, January 13th; February 10th; March 9th, 23rd; April 13th, 27th; May 11th, 25th; June 8th, 22nd; July 13th, 27th; August 10th, 24th; September 14th; October 12th; November 16th; December 14th; Whit-Monday Show, May 16th; Great Summer Show, June 8th, 9th, 10th, 11th; Artisans' and Cottagers' Show, August 2nd (Bank Holiday); Conversations, Wednesday, May 26th: Evening Fête, July 21st. The date of the Rose Show and Exhibition of the Pelargonium Society will be announced hereafter.

- THE rather smart VISITATION OF PROST that occurred in the metropolitan district on the nights of Thursday, Friday, and Saturday last will be of considerable value to nurserymen in accelerating the fall of the leaf in the case of young fruit trees. In consequence of the early and prolonged frost of last winter but little planting could be done, and the orders for trees are correspondingly large this year—orders that in the interests of purchasers it would have been unwise to have executed so long as the trees remained green and the foliage fresh. The frost departed as suddenly as it came, and the weather remains dry and the temperature mild, and planting of fruit and other trees should now be prosecuted with energy. In some gardens around London the thermometer fell to 18° during the frost, and skating was indulged in in Battersea Park and on Clapham Common, where the water was not deep.

WE are informed that Sir FRANCIS TRUSCOTT. the new Lord Mayor, has offered a valuable prize to be competed for at the International Potato Exhibition of 1880.

A MEETING was recently held in Glasgow, at which there was a large attendance of nurserymen, gardeners, and amateurs, when it was decided on the motion of Bailie Cameron to form a WEST OF SCOTLAND PANSY SOCIETY, for promoting the cultivation and exhibition of Pansies. It was also agreed that, to render the exhibition attractive, a few classes of Roses, Pinks, &c., should be added. A representative Committee representing about forty towns and villages was formed, out of which was chosen the executive Committee of Directors. The Hon. William Collins, Lord Provost of Glasgow, has accepted the post of Hon. President. The leading nurserymen making Pansies a speciality have intimated their intentions to gwe prizes, and the Society starts into existence with every prospect of success. We append a list of office bearers. The President of the Society is Bailie Goodwin, Kirkintilloch; Treasurer, Mr. McIntosh, Dennistown, Glasgow; Secretary, Mr. McCrorie, Kilbarchan; Directors, Messrs. Paul & Archie, Dunean, Paisley; Thomas Hogg, Cathcart; Storrie & Sutherland, Lenzie; Cameron & Malcolm, Kirkintilloch; Duncan of Trocchar; Gibson, Kilsyth; Stewart, Lennoxtown; Law, Springburn; McMillan, Haghill; and Borrowman, Glasgow.

WE have received two letters relative to the specimen plants at the Walton Chrysanthemum Show. One correspondent remarks on the great superiority of the first-prize collection of six dwarf trained specimens, and observes that the secondprize plants though fine, were "not in flower at all, and they ought to have been placed third." The other refers to the general inferiority of the first-prize six and the "beautifully developed blooms" of the second-prize group, which "ought to have been placed first." So much for fancy and diversity of opinion. A report of the Show will be found in another column.

AT the residence of the Misses Christy, Coombe Bank Kingston, we recently saw an exceedingly fine display of CHRYSANTHRMUMS which it is generally known Mr. Moorman grows remarkably well. The collection is a large one, and includes a great proportion of Japanese varieties, and we doubt if finer flowers of some of the varieties could be seen elsewhere. Several new varieties recently sent out by M. Lemoine are well represented. For instance, Fleur Parfait, which is of dwarf habit about 2 feet high, bearing large, full, handsome pinkish flowers; a grand variety. Bouquet Fait is a beautiful flower of a most delicate tint; but M. Ardene is the giant of its race. for the flower of the its race, for the flowers are nearly 9 inches in diameter and about 4 inches high in the centre, of pyramidal form, and a

fine pinkish hue: it is an improvement on Sultan. Among other Japanese in superb form were Kri Kang, Elaine, Gloire de Toulouse, Garnet, Fair Maid of Guernsey, Cossack, and the profusely flowering La Nymph. The incurved varieties were also in excellent condition, and in one or two instances it was difficult to imagine how the flowers could be improved, for though perfection may be unattainable they were certainly very near to it. Such well-known and generally appreciated varieties as Mrs. Dixon, Mr. G. Glenny, Mrs. George Rundle, Beverley, and Golden Beverley were bearing numerous handsome flowers. Mr. Bunn was also in good form: this is an improvement on Golden Beverley, the flower being neater and rather deeper in colour, and it deserves to be very extensively cultivated. Many other varieties are equally well grown, including some of the Anemone varieties.

—— In the stove at Holly Lodge, Highgate, the residence of the Baroness Burdett Coutts, we noted on a recent visit an extremely fine Passiflora Princers, which was trained up the rafters of the house and flowering most profusely. This handsome plant can scarcely be excelled as a stove climber, for the long pendulous racemes of bright scarlet flowers are freely produced throughout the summer and autumn months. Mr. Willard, the excellent gardener, who has had charge of this garden for many years, finds this Passion Flower of great service in affording a supply of flowers for cutting.

THE collections of vegetables from Lord Lismore's, Shanbally Castle, and Mrs. Malcomson, Minella House, the first and second prizewinners at the CLONMEL SHOW, were very large, and reflected much credit on the cultural skill of the respective head gardeners, Messrs. Wilsher and Crehan. The Chicory, Cardoons, Mushrooms, Beet, and garden Turnips of the former were as remarkable as the handsome variegated garnishing Brussels Sprouts, Cauliflower, Grove's Red Beet, and Prickly Spinach of the latter. Perhaps of greater interest to the crowds of visitors were the fruit collections of Lord Lismore, Mrs. Malcomson, and Mrs. Bianconi, who obtained prizes in the order named. As a rule half a dozen of each kind of Pears and Apples were shown, while Mr. Wilsher showed remarkably large bunches of Lady Downe's Grapes. Particularly remarkable was the fruit from Lord Lismore's, Catillac Pears and Lord Suffield Apples, while not less noticeable were Mr. Crehan's fruit. Great objects of attraction were the table decorations sent by Mrs. R. Bagwell and Dr. Hemphill; so good were they that no reference here would do them justice.—W. J. M.

The annual dinner given by Messes. Sutton and Sons of Reading to their EMPLOYES, took place on the 13th inst., when nearly three hundred sat down to a well-appointed repast in the large packing room of the seed establishment. The several tables were presided over by the heads of departments, and at the principal table were Messrs. M. H. Sutton, A. Sutton, M. J. Sutton, A. W. Sutton, and Herbert Sutton. Mr. M. H. Sutton, the senior partner of the firm, gave the guests a generous welcome, and delivered an appropriate address. Mr. Alfred Sutton also addressed the assembly. The speakers were highly applauded for the sound counsel and important advice tendered to the audience. At the conclusion of the repast the company, joined by their wives and friends, numbering upwards of six hundred persons, proceeded to the large farm-seed order room, a part of which had been divided off into a concert hall, where an admirable entertainment was given by employés of the firm, assisted by Mr. James Freeman, who presided at the pianoforte.

WORK FOR THE WEEK.

PRUIT HOUSES.

Vises.—Clearing off the foliage from late Vines will remove one of the great causes of damp. Do not, however, remove the foliage before it is mature. The inside borders should be covered with straw or mats, which will prevent the soil from cracking. Outside borders should have been covered with protective material, and shutters or lights to throw off the wet. Fires will be necessary to maintain an equable temperature, 50° not being exceeded, taking advantage of fine days to admit air freely. Look over the Grapes frequently for decayed berries, as when decay affects a single berry it soon spreads to others unless promptly removed. Vines from which the Grapes have been cut should be pruned without delay, or if the foliage be off and Grapes still hanging the bunches should be cut with a good portion of wood attached, as they keep quite as well in a dry room with the shoots inserted in bettles of water, a piece of charcoal being placed in each. In pruning cut back the shoots to plump rounded eyes upon firm ripe

wood, leaving about two eyes upon the spur system, which will afford very serviceable bunches, but if large bunches are required a few of the shoots may be left a few eyes longer. Those upon the extension system should be pruned to firm wood and plump eyes. If the top soil of the borders has not been removed down to the roots whilst the Vines were in leaf it must now be done, taking the inert top soil clear away, and dressing with good turfy loam to which may be added a twentieth each of crushed bones and wood ashes or charcoal, not covering the roots deeper than 3 or 4 inches. Beyond removing the loose bark there should not be any attempt at peeling and scraping, which does more harm than good; and a thorough washing with tepid water and a hard brush will destroy more insects than a pigment of clay and other substances, which neutralise the effect of an insecticide. If they are clean a dressing is not needed, for a good washing with water, or at most soapy water will be all that is necessary. The houses if not required for plants may be left open day and night, but the roof lights may be closed when the nights are likely to be frosty. The houses at the time of pruning the Vines should have a thorough cleaning, limewashing the walls and painting the woodwork if necessary. Frequently turn over fermenting material and replenish with fresh from the stables. Vines in pots and the earliest started Vines will be showing signs of vitality, and may have a slight increase of temperature, increasing at the same time the supply of atmospheric moisture. Very little ventilation will be necessary for some time, but air should be admitted at 65°, closing at that temperature.

Peaches and Nectarines.—If the trees in the earliest house have been started they must not lack water in the inside borders, and if there exist any doubt about this after examination water thoroughly with water slightly in advance of the temperature of the house, and if the trees are weak employ weak liquid manure. A bed of fermenting materials formed on the border will give off considerably more invigorating heat than fire heat, whilst the moisture will be more regular and conductive to the swelling of the buds than frequent sprinkling of the trees by the syringe. Fire heat should only be employed at night to exclude frost, and by day to raise it to 50°, at and above which ventilate freely. Avoid as much as possible a close stagmant vitiated atmosphere after the buds begin to swell, and sprinkle the trees and house in the morning and early afternoon of bright days until the blossoms show colour, when discontinue the sprinkling overhead, and ventilate constantly to guard against a vitiated atmosphere.

FLOWER GARDEN.**

Where it is intended to make new plantations of Roses the plants should be ordered in good time so as to secure good healthy plants. The ground should be thoroughly prepared for their reception by trenching as deeply as the good soil admits, not bringing bad subsoil to the surface, but it should be loosened, especially in shallow soils, and a good dressing of manure applied and mixed with it. It is useless attempting to grow Roses with water lodging in the subsoil. Efficient drainage is as necessary for Roses as any other plants. If the soil be light it may be permanently improved by mixing in a good quantity of clay during the process of trenching, which should if possible be obtained in a dry state and thoroughly broken up into small lumps that it may the more readily mix with the soil. Clay buried in this way is very retentive of moisture, and the Roses like it, as is evidenced by their roots clinging tenaciously to it when the plants are removed. Where the soil is naturally stiff Roses on the Briar stock succeed admirably, but where the soil is light they do not succeed on the Briar; the Manetti stock is then in every way superior to any other, the seedling Briar being no exception. On a light porous soil the Manetti is very fibrous-rooted, on which account it makes the most of any manure that may be applied in soild or liquid form. For dwarf Roses it has no equal, but is not suitable for standards. In planting Roses that are on the Manetti stock they must be planted so that the union of stock and scion is buried about 3 inches below the surface, but those on the Briar must only be planted as deeply as they have been before, or with the roots 4 to 6 inches covered with soil. After planting securely stake the standards and mulch heavily with half-decayed dung. Cuttings of Manetti should at once be made and inserted to supply stocks for next season's working. These should be made about 6 or 8 unches long, and every eye except the top one cut clean out, or they will be constantly throwing up suckers, inserting

Falling leaves will keep the broom in constant use for some time to come, although it is hardly to be expected, where deciduous trees are numerous, that grounds in their immediate vicinity can just now be kept in good order. Much may, however, be done by attention to sweeping and collecting what are down every morning before they are scattered by the wind. The roller, too, should not stand idle, as the walks, however good, are sure to be improved in appearance by having it frequently passed over them. Lawns as well as walks can scarcely be rolled too much, as it not only improves the appearance and texture of the grass, but is quicker way of removing wormcasts than sweeping. It may yet be necessary to pass the machine over the lawn once more, as the grass is apt to grow knotty and irregularly at this season, presenting an untidy appearance.

TRADE CATALOGUES RECEIVED.

Messenger & Co., Loughborough.—Illustrated Catalogue of Horticultural Buildings and Hot-water Apparatus.

Harrison & Sons, Leicester.—Catalogue of Fruit Trees and Ornamental Shrubs.

TO CORRESPONDENTS.

** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (A. C. C.).—Our "Kitchen Garden Manual" contains much information in a concise form on the culture of vegetables, and gives lists of reliable varieties. Price 4d., post free, 4½d. Mr. Shirley Hibbert's "Amateur's Kitchen Garden" is a larger work that you may read with pleasure and profit. It is published by Groombridge & Sons. We do not know the price, but it is within the amount you name. "Bee-keeping for the Many," post free from this office price 4½d., will be useful to you; also Pettigrew's book on bees, which you can obtain through a bookseller.

LIFTING AND REPLANTING VINES (6. 0. C.).—In our issue of November 6th, page 874, you will find instructions on removing Vines. If the information there given does not exactly meet your case we will on being informed of the age, varieties, and condition of your Vines and border endeavour to give you such information as will be of service to you.

endeavour to give you such information as will be of service to you.

PRESERVING CAULIFLOWERS FROM FROST (L. C. L.).—Plants just forming heads if taken up and packed closely together in brick pits, the roots of the plants being in moist soil, may, with the aid of such covering as is needed on the glass in severe weather, be kept for a considerable time. Plants with heads already formed may be kept in a shed or cellar. If the heads are large enough for use they may be cut with 6 inches of stem attached, the stems being inserted in moist soil in a dark frost-proof place, and the heads will remain in a good state for some time. We have prolonged the supply of Cauliflowers by laying-in the plants closely together in an out-of-the-way place, such as in the frame ground, and placing a foot in thickness of leaves on them on the approach of frost. We have cut the heads quite fresh and white after they have been buried a month in the manner described. A few pea sticks laid on the leaves prevent them being blown away by rough winds.

FRUIT TREES IN TOWNS (Subscriber).—You do not tell us the extent of

FRUIT TREES IN TOWNS (Subarriber).—You do not tell us the extent of the town in which you say fruit trees are said to bear badly. If it is a large town the quantity of smoke and dust will doubtless affect the health of the trees; if it is a small open country town or village, we do not think that fruit trees bear worse there than they do in the open country, provided they have plenty of light, air, and good soil. Some of the latter may be wanting in the cases you refer to.

In the cases you refer to.

FRUIT MEASURES (J. T. S.).—The following information, extracted from the "Gardeners' Year-Book," may probably be useful to you:—Half Skeve—Contains three and a half imperial gallons. It averages 12½ inches in diameter and 6 inches in depth. Skeve—Contains seven imperial gallons. Diameter 15 inches, depth 8 inches. A skeve of Peas is equal to one bushel; a skeve of Currants, twenty quarts. Bushel Skeve—Ten and a half imperial gallons. Diameter at top 17½ inches, at bottom 17 inches; depth 11½ inches. Bushel Basket—Ought, when heaped, to contain an imperial bushel. Diameter at bottom 10 inches, at top 14½ inches; depth 17 inches. Walnuts, Nuts, Apples, and Potatoes are sold by this measure. A bushel of the last-mamed cleansed weighs 56 lbs., but 4 lbs. additional are allowed if they are not washed. Vegetable measures will be found in the same work.

MARGING VINES (Idem)—Your proposed course of management is generally correct, but do not attempt to "assist" the leaves falling. The retention of the foliage is, the wood being ripe, usually a sign of the good health of the Vines. Take especial care that the inside borders are not too dry during the winter. Another good watering would probably be of benefit.

LARVE ON CHEYSANTHENUM BUDS (J. N. B., Bosedon, Cheshire).—
These are the young larve of a moth called the Gothic (Menia typica).
They are found on a variety of garden plants both in autumn and spring, frequently feeding on the Chrysanthemum in October, but generally confining their attacks to the leaves.

FRUIT TREES CANKERED (F. J.).—If the majority of the branches are in the same condition as those sent we fear your trees are beyond cure. We cite the following, relative to this disease, from the "Cottage Gardeners' Dictionary: "—"Trees injudiciously pruned, or growing upon an ungenial soil, are more frequently attacked than those which are advancing under contrary circumstances. The soil has a very considerable influence in inducing the disease. If the subsoil be an irony gravel, or if it is not well drained, the canker is almost certain to make its appearance amongst the trees they sustain, however young and vigorous they were when first planted. Canker arises from the tree's weakness, from a deficiency in its vital energy, and consequent inability to imbibe and elaborate the nourishment necessary to sustain its frame in vigour, and much less to supply the healthy development of new parts. It is quite true that over-luxuriant trees are particularly liable to this disease, but over-luxuriance is really a demonstration that the tree does not digest and secrete its juice healthily. If over-luxuriance threaten to introduce canker the best remedy is to remove some of the main roots of the tree, and to be particularly careful not to add any

manure to the soil within their rangs. On the contrary it will be well, if the continued exuberant growth shows the necessity, for the staple of the soil to be reduced in fertility by the admixture of one less fertile, or even of drift sand. If there he san excess of branches the saw and the pruning knife must be gradually applied. Nothing beyond a general rule for the pruning can be laid down. Keep a considerable vacancy between every branch both above and beneath it, and especially provide that not even two twigs shall chafe against each other. The greater the intensity of light and the frer the circulation of air amongst the foliage of the tree the better the chance for its healthy vegetation. If the soil by its angenial character induces the diseases, the obvious and only remedy is its amelioration; and, if the subsoil is the cause of the mischlef, the roots must be prevented striking into it. In all cases it is the best practice to remove the tap root. If the trees are planted shallow, as they ought to be, and the surface kept duly fertile, there is not much danger of the roots striking into the worst pasturage of the subsoil. Scrubbing the bark of the stem and branches with a mixture of say suds and urine, and, where any pruning has taken place, keeping the wounds covered with a mixture of clay and cow dung, are the best local application.

Pauning Vines (Sabarbas).—You may prune the Vines immediately the

PRUNING VINES (Saberbean).—You may prune the best local applications.*

PRUNING VINES (Saberbean).—You may prune the Vines immediately the leaves have fallen. You have been wrongly informed that spring is the best time for pruning, as when the work has been deferred until the sap commences moving the bleeding of the Vines is almost certain to follow. When pruned now the Vines seldom bleed in the spring. Cut the laterals to the bud nearest to the main rod that has had a leaf to support it, and shorten the leader to a length of 3 or 4 feet.

Shorten the sener to a sengen of a or a retr.

LITTLE GEM ROSE (N. W.).—This is a ministure Moss Rose, flowers of
which were exhibited by Messrs. William Paul & Son, of the Waltham Cross
Nurseries, at one of the meetings of the Royal Horticultural Society, and
were greatly admired by many visitors. It is a distinct and charming addition; and if it is a good grower, and we have no reason for doubt in that
respect it is worthy of a place in many gardens besides your own, and will
be very valuable for affording flowers for bouquets, button-hole, and was
decoration.

DWARF HARDY FUCHSIAS (Old Render).—We do not know to what Fuchsias you refer. Except in the mildest district of the kingdom all Fuchsias die down during the winter, and usually grow again from the roots in the spring. Some hardy Fuchsias with small flowers are Riccartoni, ecccinea, gracilis, and globosa, but neither these nor any others of the genus are suitable for spring bedding.

YEW BERRIES (J. Byron).—In the case lately reported in the papers of a boy dying in consequence of eating Yew berries gathered in the Cemetery of Holywell, Oxford, we conclude that he swallowed the seeds or kernels, as the pulp is harmless.

pulp is harmless.

HEATING A GREENHOUSE (W. Edwards).—Unless the structure is very much exposed, one row of 4-inch piping quite round the house will keep out the frost; but two rows would be very much better, as in growing plants for market a good command of heat is most valuable, an it is true economy to provide it. At the point nearest the boller we should enclose the pips in a brick or stout wood box to be covered with moveable yet well-fitting lights, and by filling the enclosed space (first covering the pipes with rubble or stout wooden slabs), of the requisite depth with coose-nut fibre refuse, you would have a very serviceable propagating case. A portion of the house at least should be furnished with a flat stage, placed about a foot from the glass in front for the accommodation of small plants. Larger plants would do very well on the floor of the house. By having tressles and moreable planks you could readily increase or diminish the staging according to requirements. You had better consult an inormonger as to the elbows and connections requisite for affixing the pipes to the boiler. The pipe may either be put together with indiarubber rings, when they are easily moveable, or with old rope yarn and cement.

HEATING MUSHROOM HOUSE (E. T. S.).—We have had no experience of

HEATING MUSHROOM HOUSE (E. T. S.).—We have had no experience of beating Mushroom houses with parafin stoves, and should scarcely think they would answer the purpose. The heat from the stoves is dry, and there is more or less of unpleasant smell when parafin is burnt in such a close place as a Mushroom house. If the walls and roof of the house are thickly thatched, and the beds are well covered with light dry hay, which should be moved frequently yet carefully to prevent its adhering to the surface, you may succeed in growing Mushrooms without a stove. A heap of fermenting materials in the house would be valuable by affording a genial heat.

PLANT COLLY MORDER (EMILIANCE)

PLANT COLLECTORS (Philodendron).—Plant collectors must be competent packers, and must engage assistants, and be able to manage them in the countries which they visit. Collectors for the large nurserymen not infrequently engage from one to three hundred men as assistants in searching for and gathering plants and conveying them through the jungle to the coast. A collector must have an intimate and extensive knowledge of plants and their value; he must also possess courage, enterprise, and tact, as well as have considerable capital at his disposal for the successful prosecution of his duties.

his duties. A AUSTRALIB (A Subscriber).—The plant would no doubt break again were it cut down to within a few inches of the soil, but we should not cut it down until the head has rooted, as it will by cutting the stem about half through a few inches below the lower leaves, covering the incision and the stem above it thickly with moss, which should be kept constantly most; and when the roots are emitted, as they will in the course of a few weit, it may be detached just below the notch and potted. The old stem will also break again, and when the shoots are a few inches long they may be detached with a heel and inserted singly in sandy soil in small pots, placing them in brisk moist heat, fin which they will soon root. The plant will lift with perfect safety, and may be useful for furnishing a conservatory. It does not require a stove but greenhouse temperature.

does not require a stove but greenhouse temperature.

WARM CONSERVATORY (A Lady Gardener).—A temperature of 80° is much too high for Camellias, and is sufficient to account for the bods falling. Stove plants generally would succeed in such a temperature, especially plants with fine foliage, such as Palms in variety, Dracenas, Crotona, &c., with dwarfer plants for "under growth," Ferns and Lycopodiums being very suitable. The only way of supplying moisture is by evaporation troughs kept full of water on the hot-water pipes, and damping available surfaces twice a day; but this will not be sufficient to keep down red spider, syring groverhead being necessary, and the application of a insecticide with sponge or syringe will be needed to keep the pest in check. Manderilla suaveolens will be suitable for the front uprights. Such a bouse may be rendered gay during the winter with such plants as Poinsettias, Euphorbia jacquiniseffors, Gesneras, various Begonias, Branthemums, and other plants.

CUCUMBERS, MELONS, AND TOMATOES (C. Z.).—A house such as you describe is well suited to the cultivation of either Cucumbers or Melons. The former would probably be the most profitable, as the demand for good Cucumbers is always great in London and other large towns early in the season. We shouldsow the seed in January, and grow the plants in pots in one of the divisions until strong enough for planting, and we should not allow them to bear heavily until they had covered a good portion of the trellis. They would then be strong, and with frequent surface dressings of rich rough soil and manure, and copious waterings with liquid manure occasionally, would bear prodigiously until August or September, the fruit being cut as fast as it attains market size. Immediately the plants commence waning, or the price of the fruit decreasing, you might sow seed of Tomatoes, and have strong sturdy plants ready for taking the place of the Cucumbers when these were no longer profitable. The Tomatoes would speedily commence bearing, and if needed would, with good cultivation, produce ripe fruit throughout the autumn and winter. The consumption of Tomatoes is increasing, and, owing to the disease affecting them, their outdoor culture is decreasing. Telegraph is probably the best market Cucumber, Blue Gown being a fine dark fruit. Good Tomatoes are Hathaway's Rxcelsior and the old Large Red. If you grow a few Melons Eastnor Castle, Green-fiesh, and Gilbert's Victory of Bath are free and good varieties. It is impossible to answer your question relative to the value of any or all of the above crops, as so much depends on culture and facilities for marketing the fruit.

EXHIBITING CHRYSANTHEMUMS (E. C.).—Without the name and address of the writer accompanying it, not necessarily for publication, a letter of the nature of the one you have sent us is not admissible to our columns.

COTONEASTER BERRIES (W. P. B.).—The fruit of the Cotoneaster is not poisonous.

REMOVING TREES (Day Gardener).—As you have occupied the garden by raising and growing fruit trees for sale you can remove the trees, as they are part of your stock in trade.

part of your stock in trade.

NAMES OF FRUITS (J. S. G.).—1, Red Doyenné; 2, Trout; 3, Vicar of Winkfield; 4, Nouveau Poiteau; 5, 8t. Germain. (A. P., Dorset).—6, Chaumontel; 10, Nouveau Poiteau; 15, Beurré Sterckmans; 16, Winter Greening; 17, White Doyenné; 19, Marie Louise; 21, Moccas. (Claremont Llunychm).—Apples: 2, Dutch Mignonne; 3, Cox's Potmona; 4, Braddick's Nonpareli; 6, Court of Wick; 7, Alfriston; 9, Caraway Russet; 14, Dutch Mignonne; 3, Dumelow's Seedling; 4, Emperor Alexander; 5, Not known. Pearre Beurré Boso. (A. Z.).—Pear Beurré Capiaumont; 1, Paradise Pippin; 2, Pearson's Plate. (F. Tuylor).—Apple: Manx Codlin. Pears: 1, Maréchal de Cour; 2, Louise Bonne of Jersey; 3, White Doyenné; 4, Not known. We do not name Potatoes. (W. H. G.).—1, Jersey Gratioli; 2 and 4, Vicar of Winkfield; 3, Not known. Apple: Cox's Pomona. (H. S.).—1, Nouveau Poiteau; 2, Brown Beurré; 3, Beurré d'Aremberg; 4, Beurré Superin (E. L. M.).—1, Apple Golden Noble; 2, Vicar of Winkfield: 3, Fondants de Malines; 4, Marie Louise; 5, Not known; 6, Uvedale's St. Germain. (North Clay).—Bess Pool. (C. R. S.).—1, White Doyenné; 2, Bergamotte Cadette. (South Devon).—Pears: 2, Beurré Clairgeau; 3 and 7, Beurré Diel; 10, Comte de Lamy. Apples: 1, Emperor Alexander; 2 and 4, Royal Russet; 6, Margil. We cannot name more than six varieties.

NAMES OF PLANTS (Tweedside).—Aster Novi-Belgii. (W. M., Suffolk).—Salisburia adiantifolia, the Maidenbair Tree, a native of Japan. (R. S.).—It is, we think, Plumbago Larpentee, but the flowers were much crushed. (Someraet).—I, Solanum nigrum; 2, Mercurialis annus; 3, Geranium molle. (A Subartiber).—Pteris argyrea, a native of the East Indies, but grows well in a cool house, yet not so well as in a stove, where it makes a very ornamental specimen. (E. C.).—40, Rhamnus Alaternus fol. var.; 41, Cupressus Lawsoniana; 42, Thuja occidentalis; 43, Cotoneaster microphylla; 44, Juniperus recurva; 45, Quercus Gramuntia; 46, Quercus Ilex var.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE APPLICATION OF CHALK AND LIME TO

BOTH chalk and lime are highly important factors in home farm management, and lately have not commanded the attention of farmers to which they are justly entitled. The present generation both of landlords and tenants have, unfortunately, in many instances not fairly estimated the value of these substances in the cultivation of the land. Whether we view it as a matter connected with the culture of arable land, or the management of pastures and park lands, they are the broad basis of successful agriculture; but there are numerous instances which have come within our observation in which the application of chalk or lime has been but little thought of, and consequently to the serious detriment of many estates. There are probably various reasons which have induced parties to ignore or pass over the question of chalking and liming; in some cases the distance from chalk, and the expenses attending its application, has had its influence. More frequently, we think, it has been neglected through the want of knowledge and experience of the value to be derived from its use. It will therefore be our endeavour to lay before the home farmer, not only the result of our experience of the benefit of chalking and liming of land, but the theory of their value as exhibited by chemical analysis afforded by the researches and opinions of clever and eminent agricultural chemists.

We will first consider what is chalk. We think it better to confine our definition to the actual formations of the different districts in England, Scotland, and some parts of Ireland; the most abundant of which is that combined with carbonic acid, forming a carbonate of lime, familiar examples of which are the limestone rocks, chalk, shells, corals, &c., all being of the same composition with the exception of a few impurities. In the southern and eastern part of the kingdom the most familiar is the white chalk, whereas in the north-west of England, in Scotland, and in most parts of Ireland chalk is not seen, but the same substance is in the form of a hard limestone rock. For the present we will allude to the white chalk formation, extending over an immense area, and this is divided by geologists into two—the upper and lower chalk. The first is what we meet with in the east of England; is hard and white, having numerous veins of fiint running horizontally through it. The lower chalk, which prevails in the south of England, has no flints in it, is of a softer nature and not quite so white as the upper, but much better adapted for agricultural purposes. The origin of the vast formation of actual chalk of the southern and eastern districts—which extends with some intervals into France, Belgium, and other continental States—is, we are informed by geologists, undoubtedly a sediment of an ancient ocean. If you look through a microscope at these fossil shells embedded in the chalk it will be perceived that they are sea shells, and made up of comminuted shells and corals, thus proving beyond doubt that the whole of our chalk hills are nothing more than an upheaval of the sediment of an ancient sea. Chalk is composed, chemically speaking, of lime united with carbonic acid in the proportion of 56 to 44—that is, 100 tons of chalk if burnt would yield 56 tons of lime.

the remaining 44 tons being sent off into the air as carbonic acid.

Our second consideration is, What is lime? It is best defined as an alkaline earth, an oxide of calcium, next to silica or sand being the most abundant of all earths. It can easily be procured by submitting any limestone or chalk to a white heat for a few hours; by that means the carbonic acid contained in them is expelled, and a white caustic alkaline earth is the result. When, however, exposed to the air it rapidly absorbs moisture, as also carbonic acid, thus returning to its previous composition. Before referring to the uses of lime it may be well to notice some of its salts, at least those relating to agriculture. Lime is found in some parts of this country in large quantities united with sulphuric acid, forming sulphate of lime or gypsum, which is, when ground fine, used largely in some parts of the country, and sown broadcast over saintfoin, often with astonishing results. One more combination may be mentioned, as it is the principal one of all—that is, phosphate of lime or bone earth, composed of lime fifty-four parts, and phosphoric acid forty-six parts. Phosphate of lime is, however, the most costly compound of any we have referred to, from the fact that, unlike the others, we have no natural deposit of any extent in this country. In Spain and America rocks of apatite or phosphate of lime exist in considerable quantities, being, however, not situated so as to bear carriage to this country, therefore our supply of bone earth must be looked for principally from the collection of bones of animals in this and other countries.

We will now return to our subject proper—the use of lime and chalk to agriculture. In the first place it is of use in a direct way—that is, actually as food for plants growing on the soil. Analysis teaches us that all plants contain a certain amount of lime, either more or less, according to the nature of the plant, and also the soil on which it grows. On the average a fair crop of wheat will carry with it per acre in the grain and straw about 14 lbs of lime, a crop of barley 17 lbs., of clover 110 lbs., of turnips 67 lbs., making a total 208 lbs. of lime, equivalent to 387 lbs. of chalk—say 3\frac{1}{2} cwt., taken from an acre of land farmed upon the four-course rotation, in the space of four years—that is, supposing the crops were all carried off the farm. Of course, we shall have to make an allowance for the straw and hay returned, as also for the turnips fed off on the land or consumed by cattle, &c., in the boxes or sheds. This is quite sufficient to show that in case we go on continually carrying away more lime from the soil than we return we must eventually exhaust it; therefore for the actual food of plants it is essential that occasional dressings of lime or chalk should be applied to the land. But lime acts in various ways; for instance, you sometimes hear the expression, "That piece of land is sour." Very true, probably it is sour—that is, it is acid, and requires neutralising by an alkali. Lime is the very one for the purpose, by forming a salt of lime. Again, where forests have been grubbed, or fir plantations cut down and the land brought into cultivation as arable ground, in both these cases there is a very large quantity of vegetable matter present in the soil, the natural result of the falling leaves in former years. Such land is not brought to develope its full powers of production until after the addition of a good coating of lime—say 10 tons per acre, to be repeated at intervals of a few years. In this case quick or caustic lime is preferable, as it assists the decomposition of vegetable ma

home farmer, to continue our remarks as regards the practical application and usage of the substances of which we are treating. In so doing we would observe that the changes would take place exactly the same if it were chalk instead of lime added to the land. When quicklime is put in it rapidly absorbs moisture, then carbonic acid, and very soon returns to its natural state, with this difference, however—that if put on as chalk it would be in lumps, whereas now it is in the most divided form possible; therefore when chalk is used instead of lime it must be in much greater quantities to produce the same result. The question then naturally arises, Which is most advantageous to apply, lime or chalk? This must depend entirely upon the locality and purpose for which it is required, because chalk is often applied where it is intended to perform a mechanical action as well as chemical. For instance, in heavy stiff land the small knobs serve to lighten the soil, thereby causing it to work better, and also to allow the rain water to percolate more readily through the land to the subsoil beneath, whereas lime being divided when slaked into such fine particles performs but a slight mechanical part during tillage. Again, when chalk happens to be near at hand and the carriage not so much an object, more especially in localities where the lower chalk is available, for it being without fiints a few frosts in winter will quickly divide it into fine particles, and in such cases chalk should be preferred before lime.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour .- Wheat-sowing will still be the principal work for the horses, and on some farms it will continue to be so until the middle of the month of December, and even later upon those light and dry land farms where roots are being fed off by sheep and where the custom is to sow spring or late wheat. the present prospect of farming and prices, however, we cannot recommend the home farmer to sow a long lain of wheat, the work extending into the new year. We should in preference look to barley as the most profitable under such circumstances, if the land and climate should be suitable for its growth. If the weather should prove dry enough for the scarifier to work, where the land intended for roots is foul with couch or water grass a considerable quantity may be got together and cleared off the land, not by burning, but by carting it away to rot in heap at intervals during the late wheat-sowing. If this cannot be done in consequence of adverse weather it will be best to fallow plough the land a good depth which is intended for potatoes, mangold, &c., unless it should be very foul, in which case it would be better to rafter plough. Run the rafters back early in the spring, and by that means keep the couch, &c., upon the surface, and deal with it by burning or carting away during the first favourable weather. If the land is depth, so that the land may be neith by frost, &c. The same method of applying horse labour may be adopted when it is intended to sow barley after wheat, for we cannot advise the home farmer to neglect the growth of a full lain of corn for sale, notwithstanding the low prices of grain; for in the event of next year's crop of cereals being an abundant one the acreable result may be good at low prices. Nor can we agree with the idea of "Stock rersus Corn. as we have often noticed as matter for discussion at the farmers' clubs, because it has not been shown that green or root crops could be made a profitable substitute for cereals. We have always conic be made a prottable substitute for cereals. We have always considered that although by good management a profit may be made by the feeding of stock in some seasons, yet, as it is usually carried out, it only proves to be a preparation of the land for the growth of cereals, whereby the profit on stock will about cancel the cost and charges of producing the roots, grass, &c. At odd times when the weather is open and mild the mangolds and other costs which may have here transcravill beaued in the fall should be costs. roots which may have been temporarily heaped in the field should now, in case they are not required to be consumed upon the land, be carted away to the store or heap and covered-in for winter use.

Hand Labour.—The feeding of cattle in the boxes will still be continued. Many are now, however, ripe for sale. Whether they have been grazed upon the pastures during the summer and since been well fed under cover, or whether they are two or three-year-old animals and have always been fed under cover, they will now be ready and fit for Christmas beef, and will probably make a good price. The shepherds have lately been attending sheep on turnips with greater advantage than at any time during the summer in consequence of the land being drier. During the greater part of the year sheep have suffered very much from lameness, more particularly the short-woolled stock, the various breeds of Downs and crossbreds. It may now be fairly assumed that the lameness, irrespective of actual foot rot, will occasionally occur when the weather and the land are wet and unhealthy for the animals, in consequence of the sheep having been bred for so long a period from animals affected constitutionally with the lameness. We well remember the first outbreak in 1829, and the flocks in various parts of the kingdom have never been entirely free from it for any length of time since. We also well remember that from 1826 to 1839 we were always troubled more or less with foot rot and sometimes the louer, which is an ulceration of the skin

just above the hoof. These complaints always yielded to the remedies which were applied, and never affected the sheep constitutionally or their general health like the epidemic lameness; nor did the foot rot produce abortion at lambing time as the epidemic has frequently done, to a serious extent in some seasons, during the past forty years. We, therefore, in the future recommend the home farmer to make his calculations accordingly, and always be prepared for an outbreak when the season is favourable to it. In the management at the homestead, and particularly when straw is scarce, it is recommended that as little straw as possible should be used. There will always be a portion of straw only partially soiled or saturated with urine when removed from the cart-horse stables, all of which may be daily used for littering the pigaties. Thus it will answer a double pupoe, for it will keep the dung store or heap in better condition, and be found quite sufficient for use in the pig pens; besides which, after having served its purpose in the piggery will on removal make manure of improved value compared with its having been allowed to form part of the stable dung heap, where it often remains to the detriment of the manure by becoming blue-moulded or fire-fanged.

CLUB-ROOT IN TURNIPS-CHALKING.

HAVING felt greatly interested in reading the paper by Mr-Wilson on the club root in turnips in a September number of the Journal, I gave it to a farmer who formerly had much trouble with his crops, whole acres of turnips some years being utterly destroyed by clubbing, his land chiefly consisting of a sandy soil. He has this last few years gone to great expense in giving the land a dressing of chalk; he advocates about 40 cubic yards to the acre. He says that it has effected a cure; it has so far arrested the disease at the present that there is but an occasional plant that shows any sign of it where the chalk has had time to act, and at the same time it has proved of great benefit to the corn crops. In one of his fields he has left a portion without a dressing, and there the last time it was turnips they were badly clubbed, and the corn crop since was very inferior to that chalked. As the disease is caused by a weevil, I should like to know in what way chalk acted as such a powerful preventive. Any further information on such an important subject would, I believe, be eagerly read by many.—G. L-

THE CRYSTAL PALACE POULTRY SHOW.

THE great event of the poultry year has once more come round. The revived series of Crystal Palace shows has completed its decade. Again we see in the great building an exhibition at least equal to any of its predecessors. The last few dry weeks seem to have done much towards helping on the growth of chickens, and, to judge from the exhibits, the year has been favourable to the moulting of old birds. The Palace is not this year, as last, divided into two sections by a circus, but the whole building is open to the Show, and the Pigeons have their former position in the central transept; facing them, and close to the Handel orchestra, are arranged many ingenious and ornamental poultry contrivances, prominent among them being those of Messrs. Boulton and Paul. Hard by are a goodly array of baskets competing for the prizes offered by the Poultry Club, of which we will speak hereafter.

Dorkings are of course in their old position, and more than hold their own. The old cocks struck us as being much better through the moult, and in much finer condition than usual. They number seventeen as against fifteen last year, and are generally superior. The cup (T. C. Burnell) goes to a huge bird, good all round, of medium darkness of colour; second (J. A. & M. F. Suyth) a deep-bodied broad bird and vigorous-looking, a little dark in feet; third (Rev. E. Bartrum) a short-legged and massive bird much to our fancy, as is also the very highly commended cock. Hens are about the same in numbers as last year. The failing in Dorking hens, both coloured and Silver-Grey, now is darkness of feet, which curiously is much more striking in them than in the other sex. The first hen (Smith) is very large of the tall type of Dorking, good in colour and fairly white in feet; second (Taylor) a round-breasted good bird, much such a one as Mr. Parlett's, so often showed successfully here; third (Taylor) good in size but apparently very old, her feet white but toes not well put on. We did not like the fourth-prize hen (Gladstone), her feet are poor and dark, and she is rather decrepid. Mr. Parlett's rose-combed hen might well have been noticed. 26 (B. Smith), a good rich-coloured bird; 30 (Smyth), a fine hen. Cockerels seem to us on the whole far shorter on the leg, and better Dorkings than we have often seen of late years. The cup goes to a fine deep bird well worthy of his place; his comb is his least good point, the serrations not being even; second a fine white-footed cockerel, specially good in comb; third a nice round-breasted, short-legged cockerel, second we fancy at Oxford, his only fault some white in tail; fourth a fair all-round bird with whitish feet; the fifth we did not like, his feet are very dark and his ears white, his legs are short, and form good; 39 (Smyth) is we think the

Hemel Hempstead winner, looking well but unnoticed; 51, very highly commended (Roper), a large bird; 52 (Sir A. K. Macdonald), another very large bird unnoticed; 58 (Miss Spedding), very highly commended, short-legged, toes too dark. In the pullet class there is nowadays great uniformity in colour, which is rich and good, but unfortunately also uniformity in feet, which are nearly all but unfortunately also uniformity in feet, which are nearly all dark. We went most carefully over the class of thirty-one and could only find four birds really white in feet. The cup bird (Taylor) is large and good, but not quite so good in this fatal point as she might be; second (Smyth) sprightly and rosy, and good in feet; third (Smyth) rich in colour, one of the whitest in feet; fourth (Smyth) small but very pretty in colour; fifth (Taylor) good in size with full round breast. 96, R.C. (Smyth), fine colour, form and size, but spoilt by the colour of her feet. Silver-Greys are all good classes. The cup cock (Ogilve) is very silvery, but his feet are in a wretched condition; second (Rev.

silvery, but his feet are in a wretched condition; second (Rev. R. H. Morgan) good in colour, deep-bodied, but with a poor comb. We much preferred the third—the cup cockerel of last year—not We much preferred the third—the cup cockerel of last year—not quite through the moult yet. In hens first (Boissier) is a small short bird, good in colour; second (Ogilvie) a nice bird; third (Buttlidge) a large hen, but evidently old and with indifferent toes. The cockerels make a large class, though there are few very good birds in it. The cup goes to what we may now call Mr. Boissier's well-known winner, looking well though his tail has not grown straight; a silvery pretty bird, but with a bad toe. Third (Fellowes), a neat small-framed cockerel; 183, highly commended (Ogilvie), one of the finest birds in the class, but with some brown on the wing. Pullets number twenty-three, and are the best class of Silver-Greys. First (Cresswell) a beautiful bird all round, with really white feet; second (Mrs. Wacher) pretty good but dark in feet; third (Ogilvie) a fine short-legged, but feet again too dark. There is no class of poultry which we consider to again too dark. There is no class of poultry which we consider to have improved more of late years than Silver-Grey Dorkings. The dingy rusty hens which formerly appeared, and often won too, would now have no chance. The Cuckoo class is well filled, and with fine birds, though many of them fail in combs and feet. First (Young) very perfect in marking, though the cock has a horrid comb; second (Young) large birds, too light in colour; third (Lady Dartmouth) smaller but pretty. The other pair, too, shown by Lady Dartmouth are very well marked. Whites keep their by Lady Dartmouth are very well marked. Whites keep their position, but do not become more numerous. The cup for the best White or Cuckoo is properly given to the first White cock (Cresswell) a fine, very white, and symmetrical bird. Second (Pilgrim) is small but white; third (Cresswell) by far the largest bird in the class—the cup bird of last year, but not well moulted in tail. The first hen (Cresswell) is far shead of the rest; second (Mra. M. A. Hayne) a fine hen, but in the moult. Third (Cresswell) a very white, large, and square bird, young-looking; 192, highly commended (Stratford), a good bird with nice comb. As usual the five-guinea selling class contains a number of ill-matched pairs. five-guinea selling class contains a number of ill-matched pairs. In the first-prize pen of Darks is a nicely shaped cock, but bad in feet; in the third a large white-footed cockerel, but mated with a poor pullet. Mr. Teebay judged the Dorkings, and his awards were well received by fanciers.

Cockins.—The Buffs are large and fine classes. The admirers of this variety seem never to tire of it, for year after year we see much the same names to the fore. The four classes collectively number no less than 107 birds. The cup cock (Rigg) is a grand bird, beautiful in colour and fuff, and short-legged; a grand bird, beautiful in colour and fluff, and snort-legged; second (Percival) a taller bird, but good in colour, a little too much inclined to the objectionable tricolor; third (Wright) very large, but showing white on the wing, and much white in foot feathering, and with too black a tail. There are many good hense in the next class. First (Burrell) a beautiful canary-coloured bird, of such a hue as is seldom seen after the first moult; second bird, of such a hue as is seldom seen after the first moult; second (Tomlinson) capital in shape, larger than the first, and of a medium depth of colour; third (Dixon) very short on legs, with fine fluff, but not enough foot feather. Beyond the winners are many hens worth notice. 287 (Swindell), very highly commended, pale in colour but well shaped; 247 (Burrell) a good bird, though unnoticed. No less than thirty-four cockerels compete. The cup goes to Mr. Wood's now well-known bird, short-legged and shapely, though we never admire the white in his wing; second (Swindell) a good bird all round, of lovely rich colour; third (Bobin) very deep in colour, though not really a Cinnamon. We do not like a mixture of Buff and Cinnamon. The fourth-prize cockerel (Cockroft & Ashby) was the best in the class; he is a large bird, dark in colour, deep bodied and fluffy, but loose in wing. Space fails us to notice many birds in the class; he is a large bird, dark in colour, deep bodied and fluffy, but loose in wing. Space fails us to notice many birds in this class which deserve mention. 268 (Mrs. Christy), though small, is very pretty in colour; 267 (Pye) even in colour, and a promising bird; 268 (Clatworthy) very rich in colour, though black in tail; 284 (Rice) very highly commended, pale in colour, but very fine. The first pullet (Pearcy) is, we think, well ahead of the rest; she is fine in shape and even, though not bright in colour. Second (Lady Gwydyr) a very small bird, certainly lovely in colour, but we prefer her ladyship's very highly commended pullet; third (Mrs. Paxon) is good all round, even in colour, but we do not like her hocks; fourth (Bloodworth) a pretty pullet, a real Cochin in shape, but not large. pretty pullet, a real Cochin in shape, but not large.

The Partridge classes do not come up to the Buffs in numbers. The cup cock (Percival) is a grand bird in splendid condition; his colour is rich and his fluff deep; his legs might be shorter. Second (Wood) an immense old fellow, deep and large, he is hocked and his comb not very good; third (Percival) is not through the moult in hackle, otherwise he is in good condition. The hens are another good class. First (Wood) is a good bird with capital breast pencilling, but our own fancy leads us to prefer the second (Mrs. Turner) a bird with beautiful even pencilling all over, and in perfect condition though she might have better foot feathering. (Mrs. Turner) a bird with beautiful even penciling all over, and in perfect condition, though she might have better foot feathering. The first cockerel (Sharpe) is such a bird all round as is seldom seen; in colour, gloss, and depth of body quite perfect. Second (Wood) a broad heavily-feathered cockerel, not in trim condition; third (Wood) a broad nearly-teathered cockers, not in this condition; third (Wood) small, but shapely and fluffy. The pullets were placed in one of the upper tiers of pens, where it is almost impossible to judge them well. First (Wood) struck us as being only a fair bird in both size and shape; second (Fowler) a good pullet but too high in comb; third (Brown) the best marked pullet in the class; we liked Mr. Sharpe's very highly commended

The six White cocks all have cards. First (Percival) a very The six White cooks all have cards. First (Fercival) a very white bird, and splendid in foot-feathering; second (Mrs. Holmes) a broad big bird, good in fiuff, but failing a little in shank feathering; third (Wood) a fine old bird not well through the moult. Mr. Tomlinson's bird is a little yellow, or must have run the third-prize bird hard. The White hens are, all round, the finest class of the kind that we have ever seen. The first and-cup (Mrs. Turner) is not very large, but very pure in whiteness; second (Fowler) an immense bird not fully moulted; third (Dr. Szell) all round, in our opinion, the best hen in the class, being fine in size and all that a Cochin hen should be in fluffiness. She was claimed, we believe, by a good judge for ten guineas. The first White cockerel (Darby) is decidedly the best White Cochin cockerel we have ever seen, and almost a model bird in every point. The second (Ludlow) the famed Oxford winner, which has changed hands for very high figures, does not come near the first, though we before thought him almost unequalled. Third (Cockroft and Ashby) a bird of somewhat the same type, though not so white. We hear that he came from the same Scotch yard, and that £27 has lately been refused for him. The pullets are not so remarkable as the cockerels. First (Darby) a beautiful bird with possibly a little too much tail; second, belonging to the same exhibitor, very large and broad, and to our fancy decidedly better than the other, though not so well shown.

other, though not so well shown.

The classes for Blacks are this year called "for Black or Langshan." All the winners are of the improved type of Cochin, and doubtless the Langshan fanciers are not gratified. For some time Black Cochins made very rapid strides, but just now the breed seems somewhat stationary. In cocks, first (Miss Lightfoot) is an enormous bird, good all round; second (Mrs. Holmes), pretty, rather small; third (Darby), a well-known winner as a cockerel last year, good in shape and feather, a little damaged in comb. The first hen (Mrs. Aspden) is good in shape and fairly green, her legs are vellow: second (Darby) closey and handsome, failing in The first hen (Mrs. Aspden) is good in shape and fairly green, her legs are yellow; second (Darby) glossy and handsome, failing in leg feather; third (Darby) in beautiful blooming condition, good in fluff and cushion, but short of foot feathers. The first cockerel (Darby) is, like his owner's hens, in lovely condition; he is certainly the best cockerel, though longer than we like in back. Second (Badger) a good bird all round, inclined to white ears; third (Darby) very heavily feathered. The pullets are more numerous than the cockerels. First (Mrs. Turner), very shapely and green; second (Unsworth) large and glossy, and if only of the age she is entered at (five months), a wonder; third (Darby) a pullet which promises to make an immense hen.

which promises to make an immense hen.

Cuckoos numbers but five pens, all belonging to one exhibitor, Mr. J. H. Cuff. The first pair are good in marking, the hen somewhat bigger than her partner, which does not look well in a pen; second poor in condition but more Cochin-like in feathering; third but an indifferent pair.

The Selling class is an immense one. We are not fond of these selling classes, believing them to be mediums through which faulty birds are largely palmed off on the ignorant and unwary. There are, however, many nice pairs in this class, from exhibitors, too, who would not put in really useless birds. First (Fowler) are Whites, somewhat yellow, which we do not admire; second (Mrs. Christy) very pretty Buffs, rich and bright in colouring; third (Buckmaster) Buffs again, cheap at their price. We were surprised to see a capital pair of Blacks, shown by Mr. Darby, unnoticed. The Cochin classes were judged by Mr. Dixon.

Brakmas.—Most of the birds are placed in the upper row of pens; and the judging must have been most difficult, as the light was in some cases very bad, and in others the birds were so high up that they could not be easily examined. This may perhaps be some consolation to those exhibitors who were unsuccessful, and may also explain to those who were absent the reason why some of their birds did not rank as high in the prize list as was expected of them. Old Dark Brahma cocks number twenty, and are a good class. The cup bird (Lingwood) is the best, but we did not much like either the second or third, both having bad combs, and the second-prize bird (C. Taylor) is also yellow. Mr. Henshall's and Mr. Ansdell's birds might have taken the places of either of them, and pen 543 (Norris) might have been mentioned. The class for old hens muster twenty-three entries, and are a fairly good class; bad combs are very prevalent and spoil the appearance of many otherwise handsome birds. The first (Clarke) is the best all; round, but the second (Norris) we thought rather better in pencilling, and might have won if she had more foot feather. The fourth-prize bird (Lingwood) we prefer to the third (Peake), being less brown and a better comb. There are strong classes of Dark Brahma cockerels. The Black-breasted birds number forty-one, but show very badly, being placed in the upper row of pens. We do not like the first-prize bird (Wood) much, as he is badly bocked and has a coarse head. Second (Lingwood) is much better in nearly every point, and the same exhibitor's unnoticed bird (602) is a very good one. The third (Dr. Earle) is a pretty cockerel, also the fourth (Norris) which will improve with age. The fifth (Hon. Mrs. Hamilton) is a good bird though hocked. There are only two commendations given, and we thought more might deservedly have been given; pen 603 (Norris) unnoticed, is good. Mottled-breasted cockerels number thirteen and are a poor class, the winner (Lingwood) being the only noticeable bird amongst them. He is a well-made and very evenly mottled bird, and doubtless will be useful for pullet breeding. Pullets are a large class of fifty-one entries. The cup winner (Percival) is a very good one, well feathered and well-marked, but not so good in ground colour as some Mr. Percival has shown in past years. Second and fourth both fall to Mr. Bennett, and we rather prefer the latter of the two, as she is well-marked bird. The fifth (Fullarton) and sixth (Lady Gwydyr) we do not much admire. Pens 631 (Skinner), 638 (Wiggins), 649 (Newnham and Manby), and 660 (Comyns) are all good birds and worthy of more notice.

The awards in old Light Brahma cocks are most inexplicable. The first two (Mead and Buckston) have the worst hocks we ever saw on any prize birds, and either third (Kendrick) or fourth (Pritchard) might very well have taken their places. Pens 702 (Mitchell) and 704 (Morgan) would have done well for third and fourth positions. Old hens are a grand and large class. The first (Lingwood) and second (Ive) are a grand pair, with very little to choose between them. The third (Wood) is very large and fine, but rather short of feather. Fourth (Stephens) a grand hen, but out of condition, and it is a question whether either of her neighbours—768 (Lady Gwydyr) or 785 (Mrs. Holmes)—might not have changed places with her with advantage. The cup cockerel (Statton) is beautiful in shape and colour, but looked rather small. Second and fourth fall deservedly to Mr. Lucas, and his unnoticed pen is also good. Sixth goes to the same exhibitor, but we rather prefer his commended bird. Pullets are a strong class, and must have been difficult to judge, being in a bad light. The cup bird (Wood) is very good in shape and colour, but rather short of feather. Second (Breeze) and third (While) also very good; in fact, there is not very much to choose between them. Fourth (Hall) and fifth (Dowker) are rather creamy. 798 (Haines) and 814 (Wood), unnoticed, are much above the average.

are much above the average.

Spanish cocks are a small class, only seven being entered. First (Jones) is a bird of fine quality of face, very good in lobe and comb; second (Bull) is rather coarse in face, and we prefer the third, belonging to the same owner, as being finer in face and of better quality than second. 890, highly commended (Fowler and Co.) is a good bird. Of hens, first (Woods) is a splendid bird, very fine in quality, fine large comb; second (Le Sueur) is also a good bird, possessing a face of very nice texture; third (Thomas) is a good hen. In cockerels, first and cup for best cock or cockerel went to Mr. Le Sueur for a bird of fine quality; the worst fault we can find is that one lobe is considerably larger than the other. In other respects he is a good bird; second (Walker) is a good-faced bird, although the face appears rather small; third (Bull) a very clean-faced, good-combed bird. Of pullets, first and cup for best hen or pullet went to Mr. J. Woods for a very good bird, aplendid in face and good in comb, and of nice size. It is questionable if second (Walker) should have occupied any position in the prize list, as the birds appear to possess male characteristics. Third

list, as the birds appear to possess male characteristics. Third (Bull) is a very pretty pullet and has a good face.

Polish.—Of Golden-spangled cocks, first (Partington) is a dark-coloured bird, and if you catch him right he looks well, but he is too black on the breast, and his tail is devoid of lacing; he has a fairly good crest. Second (Huish) is a cockerel and a very sprightly bird, good in crest, and extremely so in colour and marking; third (Sewell) is a cock of great merit, excepting that he is not in nice feather, a point in which most of the birds of this variety are lacking, as almost all the year-old birds are nothing like through the moult yet. Mr. Burrell's is a rich-coloured bird, very well laced, but he is quite backward in crest yet. Of hens, first (Tweedale) is a good crested one and good also in shape, but she is not equally good in colour; second (Boothby) is a good-crested well-marked hen, good in shape; third (Partington) is heavy in marking and not bright enough in ground colour, but she has certainly a finely

shaped crest. Mr. Scott's hen is a pretty one: Mr. Burrell's is nice in crest but deficient in colour. 1517 (Tweedale) is a handsome hen, we like her colour and marking much; 1518 (Silvestin not so good in colour and marking as in crest, which is very large; 1519 (Jarvis) is the best pullet in the class and will make a very good hen no doubt; 1528 (Unsworth) is a bird which it seems strange should have escaped mention. She is a good all-round bird

In Silver-spangled cocks Mr. Burrell is easily first with the bird which won the cup at the Palace a year ago. The bird is good in all points, and will take much beating. If he had been a month forwarder in feather he would most likely have had the cup again this year. Second (Burrell) is also a bird of very good general characteristics; if he were perfect in shape he would be a splendid fellow, although his creat is not equal to the first, as it shows a little tendency to split in the middle, still he is very fine in front and is well marked, having a very clear tail. Third (Adkins) is a long way behind in creat; 1539 (Bloodworth) and 1540 (Lady Darmouth) are both good, but neither are up in creat yet. Of hens the first (Adkins), which wins the Polish cup, is a beauty, as near perfection all round as we have seen for some time. She is large and compact in creat, and well laced all over. She deserves the cup. Second (Adkins) is very good in creat, and a well laced bird; third (Burrell) is also very good in creat, but is not so perfect in marking, being a little inclined to be mossy; 1534 (Silvester) is too dark and heavy in marking, but has a large and very compact creat; 1536 (Shepherd), unnoticed, is very fine in creat and a good bird, but perhaps a little round in the back. Mr. Cannan's hen is rather too dark, otherwise good; Mr. Bloodworth's is a very good one; and so also is Lady Dartmouth's, which is very well marked, and has a very large crest.

Through the liberality of a leading Silver Poland fancier, who offers the prizes, this variety, for the first time at the Palace, is provided with classes for cockerels and pullets. In cockerels fist Adkins) is a thoroughly snangled-breasted one and is a good bird.

Through the liberality of a leading Silver Poland fancier, who offers the prizes, this variety, for the first time at the Palace, is provided with classes for cockerels and pullets. In cockerels first (Adkins) is a thoroughly spangled-breasted one, and is a good bird throughout, excepting his shape does not seem exactly the thing. Second (Burrell) is a mere chicken yet, but he will some day be a beauty, for he appears to possess all the points of excellence of the first-prize cock. He is a very promising bird. Third (Bloodworth) is a good-shaped nicely crested bird, very lacey about the head, also well marked on the breast and wing; 1546 (Adkins) is another spangled-breasted bird, very good in crest and fine in shape, will make a very good adult; 1548 (Smith) a well-marked bird, very good in crest. The first pullet (Smith) is, we think, the Oxford winner, a very good bird, with large and compact well-marked crest; a handsomely marked bird. Second (Smith) is also a fine pullet, good in crest, shape, and marking; third (Bloodworth) a good bird with nice crest, and good in other points; 1562 (Adkins) appears to be worthy of more notice than she has obtained. She is a good bird. 1565 (Burrell), unnoticed, rather young, but very promising

promising.

In Black or Any other colour cocks first (Broad) has well camed his position when in other hands. He is a good bird, but is not thoroughly up in plumage yet. Second (Beldon) is a very good Buff Poland, or Padue Chamois, as the breed is called in France; very good in crest, and in nice plumage. Third (Unsworth) is 8 Black of fair merit, but not quite through the moult yet. In heas first (Unsworth) is a good Black; second (Beldon), the mate to the second-prize cock, both of Paris repute, a very handsome and meritorious bird; third (North) a fair bird, though smallish in crest. What could be the reason that 1584 (Unsworth) was unnoticed? Had she been too much trimmed? She looked the best Black hen in the show.

PIGEONS.

Who can say anything new of a Show which has gone on in the same place for eleven years? It is no longer a marvel that the whole of the Palace at Sydenham is once a year filled with polity and Pigeons, long nave and broad transept. At first people were surprised, now all are used to the poultry carnival and its great field days. All, then, this eleventh year is much the same as on former years—long practice has made perfect; alteration in the sense of improvement is hardly possible as to management. The place is the same, the chrysanthemums similar, and quietly in their floral beauty reminding us that Christmas is coming. One thing is painfully the same, the Palace is as draughty as ever. As to the devotees of the poultry and Pigeon world, all look much as usual. Time deals gently with poultry judges and fanciers. It think the young men are most altered; I spy grey hairs in the whiskers, but the old well-known poultry heroes are as usual. I made my first visit on Monday quite conscious that prize cards cannot possibly be up, and that judging must be going on—it could not be otherwise, and the Show is so large that the first day there must be for some hours chairs blocking the way and keeping separate; judges frightfully grave, and no little puzzled how to decide between rival beauties. A distinguished and facile write has lately told us that to see Paris properly is not to follow any plan, but carelessly to walk about and see and enjoy. This will do for a first visit to this great Show. Go anywhere just as it happens, see feathered beauty in various forms as it comes before

the eye. This I do to-day, but to-morrow it will be catalogue in hand, and pen after pen of birds in rotation examined. As to the Pigeons there are fewer than last year, but the quality has improved as a whole. There is, however, one great miss—we no longer see the large and handsome pens under the dome, each containing six pairs of different varieties of Pigeons. These were most attractive—quite the feature of the Show, and non-fanciers spent more time in front of them than in front of any other birds. Why are they gone? In their place a class, a small one, for the best pair of any variety bred in 1879. This is a sad falling-off, post pair of any variety bred in 1879. This is a sad falling-off, and a blotting-out of one chief beauty of the Show. I notice that the practical turn of Englishmen is shown in the great number of homing birds exhibited, birds of utility; and also, I fear, the pinch upon many owing to the depression in trade is shown in the immense selling classes occupying three pages of this catalogue. Such is a general outline of this beautiful Show as to Pigeons as the property of the catalogue.

seen by me on Monday.

Tuesday, November 18th, a brilliant mild morning, and I am again in the Palace. First come the Powers, and first among them the Black Pieds, which seem to be improving as to slenderness large and stout they have long been, but now slenderness is added. This property was to be noticed particularly in the second-prize cock (Bullen). A hen (Hairsine) won the cup, a very large bird and good in colour, while third-prize (Holmes) had a pretty rose wing. The Red and Yellow Pieds one is always afraid to come wing. The Red and Tenow reds one is saways sinkly to come to, as their colour is usually so unsatisfactory, but less so this year, as the first Yellow (Dye) proved. The third Red (Tenney) had colour and size. The graceful Whites came next, which have achieved of late larger crops. In the cock class first-prize (Fulton) was far ahead. The same owner took the cup for White hens, a smallish but graceful bird with admirable well-covered limbs. As to the young Pouters, they showed by the want of size in many of them the very bad season it has been for breeding. The cup cock (Holmes) an exception. Yellows appear to be on the increase. First Yellow hen (Fulton) a gem, but too gay in crop. The Pigmy Pouters seem to be becoming more popular, though some very queer-coloured birds appeared among them. A most noticeable bird was present, but not for competition; it was a black-pied bird of exactly the correct standard colours. This was bred and is owned by Capt. Norman Hill, who has been twelve years achieving this wonderful feat—a success equal to Sir John Sebright in producing the Bantams called after his name. This bird was the wonder of the Show.

The Carriers were remarkably good, and the Duns perhaps unequalled. The cup birds (Fulton, Maynard, Dye, Stephens, Jones, and Kempton) were excellent in their various properties, but perhaps slenderness of neck prevailed unusually, giving won-

derful grace.

Dragoons more numerous than ever, and beautiful in colour and form. The Yellows now show no slate colour in the tail, would that the Red did not. Mr. Bishop is still pre-eminent in brown-barred Silvers. The old-fashioned grizzled Dragoon has reappeared; indeed in all classes these birds showed well.

reappeared; indeed in all classes these birds showed well.

Almond Tumblers still deficient in colour, and chiefly head-andbeak birds. Mr. J. Baker showed a most exquisite Kite, quite
what a Short-faced Tumbler should be. Barbs were considered
among the best class of Pigeons shown. The best (Walker and among the best class of Figeons shown. The best (Walker and Baker), had the round head, and yet the long body so much needed in this variety. Jacobins good in colour and in points, but very large, except the Blacks, the cup Black (Heritage) being, perhaps, the best Jack shown. The White class, a fairly large one, was a very good one; while an "Any other colour" class brought Blues, Mottles, Dnns, and Strawberries before one's eyes—rather peculiar colours. Mr. Ure sent a true Scotch Fantail of —rather peculiar colours. Mr. Ure sent a true Scotch Fantail of the olden type, but English fanciers win with birds compounded of Scotch and English. Cup Saddleback (Taylor), very good, and coloured Fans improving. Nuns few and all Black except one, which was a Yellow. Truspeters never better, particularly those of that persevering and truly patient fancier Mr. Hutchinson. English Owls a strong class. These birds, once threatened with extinction, increase much in favour. Threatened people sometimes do. Few Foreign Owls, but an exquisite Blue (Dr. Bowes) took the cup. Turbits were most numerous. Sea-Swallows or Terns, very dainty birds of feather, had a good class; while the Magpies were most numerous and good. Archangels few. Runts fewer but of immense size. A fair lot of good Flying Tumblers. The great number of Answerps (Homers), and vast Selling classes I have already noticed.

Such was this beautiful Show. People are always apt to scorn what they do not understand, but once learn to understand the properties of fancy Pigeons, then you will see great beauty in the different varieties. They are very fascinating both as a study and a hobby, and it is therefore no wonder that a large and increasing number of ladies and gentlemen are devotedly fond of them, and find great pleasure in their culture.—WILTSHIRE RECTOR.

VARIETIES.

THE Derby Poultry, Pigeon, Rabbit, and Cage Bird Show took place on the 8th and 10th inst. at the Drill Hall, Derby.

The Exhibition, which comprised nearly a thousand entries, was the most successful one yet held. There were several features worthy of note in the fowls (especially the Game classes), Pigeons (the first Blue Pouter, and first and second Carriers) and local Rabbit classes; but there was likewise another feature unworthy of note, that of some cinnamon Canaries, exhibited by Mr. Thomas of Nottingham, which were disqualified for being painted.

A CORRESPONDENT writes to us as follows on the Clonnel Root Show—"The Agricultural Society of Clonmel and vicinity are to be congratulated on the fine exhibition of roots, grain, &c., which was held on the 12th inst. under their auspices. Some which was held on the 12th inst. under their auspices. Some splendid roots were shown that would do credit to any soil or situation any year; notably by Mr. Cheanley, Salterbridge, who obtained three first prizes, using farmyard manure and Lawe's superphosphate. Probably larger specimens in a collection, for which a special prize was recommended, were those shown by Mr. George Lane for Col. Villiers Stuart, Castletown. It would take some of the best localities in England to produce Suttons' Long Red mangolds 84 lbs. each and finer parsnips (Hollowcrown and Stone), while beans 9 feet high are something to see. Little less notable were the root exhibits of the energetic President Lord Lismore, and Lord Bessborough's, Piltdown; while the first prize for a farm collection, as in former years, went to Robert Cooke, D.L., Kettman Castle, Felhard. Sir John B. Gough won three first prizes in the grain department. Perhaps of even greater interest to the farmer representatives present were Lord Lismore's potato collection of seventeen of the best varieties grown, including Suttons' Magnum Bonum and the, now deservedly noticed in Ireland, Scotch Champion, both almost wholly free from disease." land, Scotch Champion, both almost wholly free from disease."

THE FRENCH BEETROOT CROP.—The production of sugar in France from 1st September to 31st October, 1879, according to official statement, was only 85,000 tons, as compared with 138,000 tons in 1878, 182,000 tons in 1877, and 84,000 tons in 1876.

THE American maize crop of 1879 is said to be immense. The area devoted to this grain in the States of Illinois, Missouri, Kansas, Nebraska, Iowa, Wisconsin, and Minnesota is 28,000,000 acres, which, on an estimated yield of 40 bushels per acre, will produce 920,000,000 bushels.

MODERN BEE MANAGEMENT .- No. 13. CONTROLLING SWARMING.

In my last paper I stated that the bee-keeper whose main object is honey has to choose between the non-swarming system and that of limited increase. The former was considered, as the result of my own experience, to be in a strict sense practically impossible. I shall now briefly indicate how the latter system may be carried out. By "limited" increase let us understand that stocks are not to be multiplied to anything like the extent of 200 or 300 per cent., as where natural swarming is practised without limit, but that no further increase than from 20 to 30 per cent. is to be allowed. Such an increase is desirable even when one has already reached the maximum number of stocks he when the use arready reached the maximum number of stocks he intends to keep; for, owing to such casualties as poor honey seasons, loss of queens in winter, or spring dwindling, it will generally be found that such an increase will be entirely absorbed before another honey season comes round.

It is most desirable that every stock in the apiary should be in

a position throughout the honey season of adding its due quota to the harvest, and therefore we endeavour to have all multiplication of stocks completed before that season arrives. The strong are called on to help the weak in combs, brood, or bees until all are as nearly of equal strength as possible, and generally the methods in use for preventing swarms, as described in my last paper, are employed up to the time when supers are placed on all the hives. Then, however, if not before, we find that we are compelled to yield somewhat to Nature, for swarming is a natural impulse, whatever be its immediate cause, and takes the form of a mania that nothing will usually allay short of its accomplishment. Should no swarms issue after all, so much the better. Our honey harvest will be certain if honey is to be had, and we can afford to wait till that is gathered before we proceed to multiply our stocks. But it usually happens that our best stocks will insist on "casting" just when honey is most abundant. Instead, however, of endeavouring to thwart the instinct, we judge it better to humour it. Our swarm issues and is hived in the usual manner, except that at least two or three combs of brood are given to it from the parent hive, and empty combs or sheets of foundation sufficient to fill up the hive. The swarm is sheets of foundation sufficient to fill up the hive. The swarm is now placed in its old location to be still further strengthened by the returning bees. By next day it will be seen that the bees have gone to work with renewed vigour under the pleasant delusion that they have had it all their own way. Then but not sooner we replace the supers on which they were formerly at work, and so heartily do such new swarms labour that in a few days almost as much progress is found as if they had never swarmed at all.

The parent stock must now be attended to in its new location.

It, too, has got over the swarming mania, which, however, is apt

to be renewed on the hatching-out of the young queens; so, as prevention is better than cure, we cut out all royal cells but one, or, better still, we cut out all and give it a laying queen from a nucleus. The likelihood is that we have other stocks which can well spare a comb of brood each to insert in the place of those given to the swarm. If a laying queen be at once given this stock will be ready for supering in a few days, but if left to rear a queen for itself it is more profitable to leave it unsupered; for, as the young bees daily emerge from their cradles, there is abundant storage room in the body of the hive; and as the larvæ are sealed over the whole force of bees is in a few days at liberty to forage in the fields. Such hives should therefore during the next few weeks be reserved for the extractor, and will in good seasons yield large returns.

Should another hive swarm within a day or two it should be similarly treated, except that the remnants of the two stocks may

similarly treated, except that the remnants of the two stocks may be united, making a powerful colony fit for immediate supering. Other methods of controlling swarming are common amongst advanced bee-keepers, but as they rather belong to the system of artificial swarming I do not refer to them here. I may only state my candid opinion that no system of artificial swarming yet invented can be relied on as a sure preventive of natural swarming, and it is with the latter we have supposed ourselves to be dealing in this paper.—WILLIAM RAITT.

WINTER PASSAGES-CHAFF COVERS.

THE necessity for winter passages was constantly referred to at the recent conversazione of the British Bee-keepers' Association, at the recent conversazione of the British Bee-keepers' Association, but as the meaning of the expression may not be perfectly clear to many, while many more may not see why these holes in the hive combs (for such are winter passages) should be made, a few words on each point may be both useful and interesting. Bees during cold weather concentrate, many thrusting themselves into the unoccupied cells of the comb they cover, while the rest huddle between them. The more intense the cold becomes the more they crowd together, so as to expose less surface to the effect of the surrounding air. The cluster thus formed should theoretically be surrounding air. The cluster thus formed should theoretically be globular, because the globe of all forms has the smallest amount of surface in proportion to its mass; but it will be seen that if five or six seams—i.e., layers of bees between combs, be forced to contract because of increased cold, the bees, if their combs have no tract because of increased cold, the bees, if their combs have no openings, cannot decrease the number of the seams without passing round the edges of their wax tracery. This the cold would prevent them from doing, even if their instinct would lead them to make the attempt. Thus the globular form is departed from, and its advantage lost at the very time that it is most essential, while the end seams containing fewest bees are most exposed; besides, those most tried have no opportunity of changing places with more snugly-positioned neighbours, and as a result frequently, in sharp snaps of cold, die in their cells. Ceasing to be heat-producers, as every living bee is, they fail to afford any protection to those next to them, and so frost weakening the colony has already prepared the way for its more ready conquest as the cold spell continues; but if small holes have been cut into the combs, the bees as they draw nearer together, passing through the combs, the bees as they draw nearer together, passing through the aperture, retain in some sort the theoretical form of the cluster, while the outside seams if weak in numbers join the detachment next nearer the centre, making it strong enough to defy the cold.

At the opening of last spring I saw many hives that had all but died out where winter passages did not exist. The far off seams of bees dead in the cells too clearly pointed out the necessity for these openings. But winter passages have other advantages. Upon examining a defunct hive it is often mistakenly asserted that it could not have died of starvation since it contained abundance of honey. The honey stored in the upper parts of the abundance of honey. The noney stored in the upper parts of the comb is kept continually at a tolerably high temperature by the ascending warm air and by the close contiguity of the heated cluster. The lower edge of this honey during severe cold is progressively being consumed and utilised in heat-production. When the thermometer rises the bees bestir themselves and commence carrying honey from the outlying portions of the hive to the immediate neighbourhood they are occupying; but should Jack Frost make a lengthened sojourn this carrying of supplies to the centre is prevented, and when the store lying over the cluster is gone the bees must starve, however much honey unreachable combs may contain. But if winter passages have been cut a bodily progress of the cluster is possible, and is actually made from the emptied larders towards others that instinctive industry has filled, and so not until all store is gone is starvation likely to occur. These winter passages—holes the size of the end of the finger—should be made with a penknife or gouge late in the year or they are likely to be built up again unless, indeed, the precaution is taken of inserting a curled shaving having an orifice of not more than half an inch in diameter. The position for these openings most to be recommended is about two-thirds of the height of the comb from the lower edge of it, and rather nearer to the mouth of the hive than the back. There made they will never stand out of the way of the cluster in winter quarters.—F. CHESHIRE.

OUR LETTER BOX.

OUR LETTER BOX.

NITRATE OF SODA (J. M.).—It is both a food and a stimulant. A food, inasmuch as it supplies two ingredients—nitrogen and soda; and a stimulant so far as it causes plants to extract the other essential elements from the soil required for the production of vegetation. If these other elements are absent—that is to say, if no yard or town manure, or guano, have been used for some years, there is no doubt that nitrate of soda is calculated to reduce the land to a still lower state. It is in consequence of this that we recommend to the farmer the use of the phosphates in connection with it. Under ordinary farming, however, the land usually receives a dressing of dang once in the four years, besides the applications and dressings for root enture, &c., and also the manure left on the land by feeding off roots with hay and other food; but all the experiments by Mr. Lawes and others above that the land must be in a very ligh state, and that it must contain in its composition potash, lime, &c., and the soil itself must be holding and of a good aspect for nitrate of soda to answer a fairly good purpose when applied alone. Under any circumstances it acts better and safer when applied in the spring and summer in dry weather, and in combination with the phosphates in some form or other, such as mineral or bone superphosphate, or guano containing the usual soluble phosphates.

MATING POULTRY (Brahme).—You propound a vexed questios, and one

containing the usual soluble phosphates.

MATING POULTRY (Brahms).—You propound a vexed question, and one that has never been authoritatively answered. As Sir Roger de Coverley said, "Much may be said on both sides of the question." The former belief was, you could not trust to any eggs from a pullet under the circumstances till she had laid out and become broody. It is now believed if she is removed and put with the ock from which it is desired to breat, the eggs may be depended upon after a fortnight. From experience we hold with the latter oninion.

FOWLS DYING (Mr. C.).—Your birds appear to be succumbing to a virulent attack of roup. You had better keep them under shelter, and give daily one grain of sulphate of copper to each bird, mixed in oatmeal mashed with ale, giving also plenty of green food. Any offensive discharge from the nostrils, should be washed off frequently with tepid water.

COLOUR OF ANDALURIANS (T. S.).—The face of an Andalusian fowl should be red, the carlobe white. The plumage generally is blue, as you suppose, but the hackles and back of the cock should be of a glossy dark

steel colour.

FOUL BROOD IN COMB (J. K. D.).—It would be more convenient for an examination if three or four suspected cells were sent in a small box instead of a large piece of comb in paper, as the lacter is nearly certain as in this case to get crushed. We are sorry to inform you that the comb is very bailly diseased, but since we do not know the nature of the hire from which it came it is difficult to advise, but in any case at this late date doing much is impossible. We greatly dislike suggesting the destruction of bees, but this seems in your case desirable for the benefit of the others which, if they survive till early spring, will probably rob them, planting foul brood in some of your best hives. The comb should be carefully burned and the hive disinfected if a bar-frame; if a skep, it should share fate with the combs. Any contained honey can be used after boiling as bee food or otherwise disposed of, a: it will be then innocuous. This stock may already have infected some others of your splary, so that we should strongly recommend that no food be given in the spring to which salicylic acid has not been added.

ADYSRIVIAN LOVE BRIDDS (A. H.).—The birds are imported into this

ABYSSINIAN LOVE BIRDS (A. H.).—The birds are imported into this country with their wings cropped. Do not let them be at large in a room until they have moulted-out their flight feathers and obtain wings it to fly with. Keep them in a cage until then. They belong to the order of climbers, and use their beaks and feet pretty freely. We have known them to meet with death with only a slight fall. We give our birds white millet seed, and treat them to a small plece of chewed bread and butter at breakfast time, of which they freely partake, being apparently free caters. The dead bird you have sent has not had a sufficiency of proper food.

REMARKS.

12th.—Beautifully bright clear day, cold wind; clear starlight evening.
13th.—Fine, bright, cold day, windy; clear night.
14th.—Thick white frost in early morning; cold bright day; clear starlight

15th.—White frost in morning; bright cold day; slight fog in evening.
16th.—Generally overcast, cold dull day, not a glimpse of sunshine; slightly warmer in evening.
Damp dull day, much warmer; bright starlight evening after 8 P.M.

18th.—Very clear, fine, spring-like day; hot sun.

Four days sharp frost, 18th to 16th, and warm days both before and after. No rain except a little dampish drizzle after midnight on 18th.— G. J. SYMONS.

COVENT GARDEN MARKET .- NOVEMBER 19.

THERE is scarcely any change to note this week; large supplies of foreign Apples reaching us, the bulk from Canada. Prices remain without alteration. Kent Cobs in demand.

From observations taken near London during forty-three years, the average day temperature of the week is 46.8°; and its night temperature 34.3°.

FRUIT FARMING.

INCE agriculture has unfortunately become such an unprofitable pursuit the minds of men have been turned to a greater degree than usual to the subject of fruit-culture as a commercial enterprise. It must be admitted that the general barrenness of orchards during the past three or four years is not encouraging,

yet there is no more valid reason for a cessation in the planting of fruit trees than there is for restricting the cultivation of Turnips, Potatoes, and Wheat. That the fruit supply of this country is totally inadequate to the wants of the population is an admitted fact—a fact, too, that is being recognised in a practical manner, seeing that an increase in the orchards of this country is officially recorded of nearly 6000 acres during the last twelve months. Indeed it has only to be stated

that £2,000,000 per annum is expended in the purchase of hardy fruit from America and the continent of Europe to convince all who consider the subject fairly what room there is for the expansion of the trade in home-grown

produce.

Corn-growing is decreasing in England, and the area of pasture land is increasing. It is fair to assume that the change is found to be profitable to cultivators, and this being so the land under pasture must be enhanced in value; but its value might be still further increased if fruit trees were judiciously planted in suitable positions. A reasonable number of standard Apple trees planted in grazing pastures would not materially injure the herbage; but they would in a few years, taking one season with another, pay the rent of a holding, and the pasturage would remain as profit. But tenants cannot be expected to invest in fruit culture on a large scale unless they hold the land on very long leases; for as soon as the trees fairly commenced bearing the increased value of the land would be manifest, and the rental would increase as a matter of course. For that reason yearly tenants will not plant fruit trees as a commercial speculation. But why do not landowners plant them? No investment in improving their landed property would pay them better. Instances of this system of increasing the value of land were recorded more than two centuries ago. In a "Treatise on Fruit Trees," published centuries ago. In a "Treatise on Fruit Trees," published about 1653, the author, Ralph Austen, gives the following evidence of the increase in the value of landed property by the planting of fruit trees, and quotes from a still older work in support of his statements. Alluding to the orchards of Herefordshire, Worcestershire, and Kent the old author observes, "The common prejudice against fruit trees in fields is that they spoyle the grasse, but land not being worth more than 10s. to 13s. 4d. per acre for grasse, by the planting of fruit trees upon it, was afterwards worth 30s. to 40s. or even 50s. per acre, and the fruits upon the trees may yield some £3 to £5, or some to £6 to £8 per acre." That statement does not bear any suspicion of exaggeration, but, on the contrary, seems to be the result of sober judgment, and the facts appear to have been accertained with care.

It is interesting to note the evidence thus adduced as to NO. 9/4-VOL XXXVIL, MEW SERIES

the value of fruit trees in the olden time; but what is more important is the fact that the same relative value of land under fruit and under ordinary agricultural tillage is as apparent in 1879 as it was in 1653. It is a well-known fact that much land in Kent mainly devoted to fruit culture is held at a rental of £6 per acre and upwards-land that is certainly not superior in staple and fertility to thousands of acres that I am intimately acquainted with in other localities. and let at from 30¢ to £2 an acre: and there is much land in England occupied with fruit trees in bearing that is readily let at more than double the price above quoted. It is a mistake to suppose that Kent is the only county in England in which fruit can be grown of high quality and in a profitable manner. I have seen crops of Apples on good soil in the midland counties fully equal to those in Kentish orchards; indeed there is scarcely an agricultural district in England where good farm crops are grown that will not grow excellent crops of Apples, Plums, and the various small fruits for which there is always such a great demand in all cities and populous urban districts. There is no fear of the markets being overstocked with fruit, for not only is the population of the kingdom rapidly increasing, and especially in towns, but the importance of fruit, not as a luxury merely, but as a wholesome article of food, is being increasingly recognised. The planting of a reasonable number of standard Apple trees on pasture lands in various districts would alike benefit the landlords, tenants, and the great body of consumers who are longing for the fruit that they cannot obtain. This mode of fruit-farming does not demand a great outlay in the first instance, as trees can be purchased at 1s. 6d. each and less, and if well planted in good soil, made secure against the wind by staking them for a year or two, and against sheep by loosely enveloping their stems with fine-meshed galvanised wire netting, they need no further care.

But there is other land in hundreds of parishes that is of no real value in its present condition which, if placed under fruit culture, would unquestionably be turned to highly profitable account, and that is wood land. In numerous places a portion of land now occupied with forest trees of little or no value, and scrubby undergrowth equally unprofitable, could well be spared for fruit culture without either interfering with the preservation of game or marring the appearance of noblemen's or gentlemen's estates. There are many copses that might be grubbed up with great advantage, and points and angles taken off plantations, not only without loss, but with certain gain; and the appearance of an estate would be improved rather than otherwise by

the change suggested.

In forming orchards contiguous to plantations it is essential that effective measures be taken to exclude rabbits, and this can only be done by fencing the orchards with strong galvanised wire netting sufficiently small in the mesh to prevent the smallest rabbit passing through; and the netting must also be so fixed that the older animals cannot pass under. I have had the best evidence that it pays well to place such netting round plantations of young Larch and other forest trees, and it would unquestionably pay equally well to place it round fruit trees. The best of all modes of putting down

NO. 1696 -- VOL. LXII., OLD SERIES.

netting that I am acquainted with to exclude rabbits is to bend | 6 inches of the bottom at a right angle, and lay this flat about 2 inches below the surface of the soil, and facing the side from which the animals make their attacks. Sinking it 6 inches in the ground without bending is of little use where rabbits are numerous. They usually commence scratching about 2 inches from the object, and if the soil is light they will go down a foot rather than be defeated in their object in getting below the barrier; but when they find a layer of wire laid flat just beneath the surface they soon desist from their attacks. This is the practice adopted on an estate where miles of wire have been employed during the last twenty years in surrounding young plantations, and by no other plan could the animals be excluded from the parts enclosed.

The cost of clearing woodland and preparing the land for fruit culture is no doubt often rather costly; yet if the work is well done the capital is soundly invested. It is only when the work is half done that there is any danger of it proving unprofitable. An instance of converting unremunerative woodland into a profitable fruit plantation has recently come under my notice on the estate of Roger Leigh, Esq., near Maidstone, and as the work has been done under the superintendence of one of the best growers of hardy fruit in the kingdom, Mr. Haycock-who is well known as the chief prizewinner in the classes for Apples and Pears at all the important exhibitions at which he competes-it may be usefully referred to. This orchard is 25 acres in extent, a slice taken from a wood which has probably not yielded the owner a pound since it has been in his possession, for unlike other portions of the extensive woodland of the estate it has not grown Spanish Chestnut for Hop poles, which is a profitable mode of arboriculture there; but on the contrary, like much other land in the same and other counties the timber and undergrowth were of such a nature as to be quite unremunerative. The land, however, now reclaimed, civilised, and cultivated will be of real value to the owner, will be locally advantageous in affording employment to the labourers of the district, and will contribute its quota towards supplying the dwellers in towns with health-promoting wholesome food. The portion of land taken from the wood is very small in comparison with the whole extent of woods-a small speck but a bright one in the landscape of the district. If such action were generally taken on large estates many a dull hillside might be rendered cheerful, and many acres of barren land made fruitful.

Than Kentish fruit-growers none know better how important and lucrative it is to prepare the land well for planting the trees. Not only do they find it true economy to expend a considerable sum in labour, but they also invest liberally in manure, so as to insure what is termed a "good start" for the trees—a matter deemed, and we may be sure not without good reason, of great moment. Further, the generous preparation of the land enables other crops both of bush fruits and roots being grown between the rows of the orchard trees, and these bottom crops alone give an excellent return on the outlay expended until the trees arrive at a fruit-bearing state. Even then undercropping is not always, perhaps not commonly, dis-pensed with, for it is certain that if the land is well tilled and manured crops of considerable value can be grown in fruit orchards when the trees are not unduly crowded and have tall stems or trunks. During last spring I had the pleasure, in the company of Mr. Barron of Chiswick, of inspecting a large fruit orchard which was well manured and tilled, which was occupied with Cabbages, earlier and better than any I had seen at the same date in open gardens. There were some acres of these Cabbages, and the crop must have realised a considerable sum, as owing to the severe and protracted winter the crops in open fields and gardens were greatly injured, and in many cases destroyed. On inspecting the fine full crop referred to Mr. Barron remarked that without seeing it numbers of people would never believe that such a result could be achieved under would never believe that such a result out the circumstances. It is a fact, too, that under the trees of orchards in the Thames valley hundreds of pounds worth of flowers are grown annually for cutting for the London markets—such as Violets, Lilies of the Valley, Poet's Narcissuses, Moss Roses, &c.; so that in hardy fruit culture, where the land is tilled, even if the fruit crop fails the undercrop is of value; and if fruit trees are grown on pastures there is still the grazing to afford a return. The risk, therefore, of loss in planting in suitable soil and positions well-chosen fruit trees is practically nil, while the gain over an average of seasons may be relied on as much greater than can be realised by ordinary farm cropping. There is consequently every induce the value of Tuberous Begonia flowers for buttonboles. This

ment for landlords to plant fruit trees on certain portions of their estates by way of increasing the value of their property. improving the position of their tenants, and conferring advan-

tages on the general community.

On Mr. Leigh's estate the wood and undergrowth referred to was first grubbed up. The greater portion was then thoroughly worked by the steam cultivator, and all the smaller roots possible were dragged to the surface, harrowed out, collected, and burnt. London manure (street sweepings and the like costing 3s. or 4s. per ton) was then applied at the rate of 50 or 60 tons per acre, and worked in, and the trees planted. Standard Apples were planted in rows about 30 feet spart, and the same distance asunder in the rows. Down the centre, between each two rows of Apples, is a line of Plums or Damsons; and between the Plums and Apples are rows of Gooseberries and Currants, and in some cases Raspberries. Dwarf Apples and Plums were planted in the rows between the standards, and in the spaces between the rows of trees and bush fruits Potatoes, and in some portions Mangold Wurtzels were grown.
Owing to the excellent preparation of the land, a free yellow
loam, the permanent trees have made a capital start, and the crops between them have been excellent. The small fruits and dwarf Apples will commence bearing at once, and with Potatoes and other crops will produce a satisfactory return for the labour invested. Shortly the Plums will add greatly to the profits, and will continue profitable until the standard Apple trees approach their full size, when the Plums, &c., can be dispensed with, and the ground can be seeded down or cropped as desired. The ground will be manured and well worked yearly, about 3000 tons of manure being now in heap for the purpose. This liberal manuring for fruit trees might frighten many people, but it does not frighten Mr. Haycock. trees are in an exposed position, the land being worked about a foot deep, and not in a close garden in rich black deep soil, and hence the practice adopted; but further, it is found profitable to purchase sewage from the adjoining town, and to apply it to the bush fruits; it is poured to the roots at this season of the year, and is found to be of great benefit.

The standard Apple trees had their shoots moderately shortened after planting, and will need but little further pruning. The dwarf bush trees were, and will be, judiciously pruned in late summer to insure the maturation of the wood, healthy growth and early bearing. This miniature fruit farm has been planted with the best varieties of fruits obtained from Messrs. Rivers, Veitch, Bunyard, and others, and the land which for years has been practically worthless will shortly be the most profitable portion of Mr. Leigh's estate. Why cannot landowners in other districts adopt, on a scale more or less large, the same means of improving their property?—J. WRIGHT.

ECHEVERIA PEACOCKII.

THIS is frequently known as Echeveria De Smetiana. It is a much superior species to E. secunda or secunda glauca for all purposes, especially bedding purposes, and it is nearly, if not quite, as hardy as the latter. The form of the resette is much better; the leaves are more erect, thicker, pointed, with a bright glaucous surface; the edges and tips reddish; when well coloured the latter feature is well marked. It grows very rapidly, and when seen dotted amongst the deep green Veronica repens it produces a pleasing effect. It can be as readily propagated as any species, provided it is handled properly. Select the smallest leaves and separate them from the stem as close as possible; lay them in a box or on a shelf in a moderate temperature, and they will soon first emit roots and afterwards buds, which should be pricked off carefully and thickly in pots and encouraged, using as soil loam, sand, and very finely broken potsherds in equal quantities; the result will be a fine batch in a short time. E. agavoides is another beautiful species, much resembling, as its specific name implies, a miniature Agave. The leaves are short, very thick at the base, abruptly tapering to the apices, of a sea-green colour, slightly glaucous, with the edges and tips deep chocolate brown; the rosettes grow to a good size, and when 5 or 6 inches across are very handsome. This species can also be increased in the same way as the last, being careful to select the small and young leaves, as the larger leaves do not yield anything like so high a per-centage of plants.—T.

summer I have cut scores of blooms for that purpose. Mixed [with Stephanotis bloom or Tuberoses they are very beautiful. For ladies' dress or as hair bouquets, three blooms of each, carefully arranged with a small frond of Adiantum gracillimum through the centre of the bouquet, and a frond of Adiantum cuneatum for the background, have a very chaste appearance. For gentlemen's buttonholes, one bloom with a bud attached I find the best. Anyone will find them far preferable to scarlet Geraniums, as they require no gumming and remain fresh the whole day. I have found the following varieties the best:—Sceptre, Gloire de Nancy, Monarch, Leelia, Madame Oscar Lamarche, Marie Lemoine, Raphael de Smet, and Purpurea magnifica. These grown under cool treatment have flowers of good substance. - B. HIGHGATE, Cuen Wood Towers, Highgate,

THE CLASSIFICATION OF ROSES.

I FANCY there are difficulties looming in the distance on this subject; and it will be well, I think, for all Rose-growers, at least all Rose-exhibitors, to ponder over and digest the matter thoroughly before it comes before them in a practical form. Hitherto for the purposes of exhibition we have been confined to two classes—the Hybrid Perpetuals, and Teas and Noisettes. Occasionally, but very rarely, a Bourbon has been introduced amongst the former; but Souvenir de la Malmaison is about the only one that we find in company with them, and it is not very often, especially in the Rose-showing season, an exhibition Rose giving its best blooms in the autumn. But during the past few years Cheshunt Hybrid has been very frequently exhibited amongst the Teas and Noisettes, and great dissatis-faction has been expressed thereat, as it has in so many instances spoiled the evenness and symmetry of a stand. I am nistances sponed the evenness and symmetry of a stand. I am quite willing to allow that it is a very good Rose, hardy in constitution, vigorous in habit, and continuous in blooming. But a Tea? No. It may have, and probably has, Tea blood in it, but the Hybrid Perpetual blood is so much stronger that it certainly ought not to be permitted to be placed amongst Teas or Noisettes. Then we have other Roses from both sides of the Channel: Madame Alex. Bernaix, Carmes, La Coquette, &c., from France, and the pedigree Roses of Mr. Bennett of Stapleford on this side of the Channel. In some lists these Roses are classed amongst Hybrid Perpetuals, in others they have a separate class allotted to them, as Hybrid Teas. Against this latter plan I see very grave objections. There are many other Roses which have evidently Tea blood in them of some sort or other. Take, for example, La France; no one, I think, can doubt its possessing this, but I think we should very much doubt Mons. Guillot's statement that it is a pure Tea. The whole contour of the flower is so different from any of the Teas, it is so much fuller and larger, that we may well call in question this statement and wonder why he has, after so many years, transferred it from the H.P.'s to the Teas. Then, again, Capitaine Christy has unquestionably Tea blood in it, but no one has as yet proposed transferring that to Teas, while a Rose I saw exhibited by Lacharme at Brie was assuredly a cross between Sombreuil and a Hybrid Perpetual. Who, then, is to decide as to which class these are to be shown in? again, there are Mr. Bennett's pedigree Roses; some of these have more Tea blood in them than others, while some are hardly distinguishable in growth and foliage from many Hybrid Perpetuals which we already have in growth. Are these, then, to be classed according to the statements of the raiser or according to the appearance of the flower and foliage? One can easily see to what endless confusion this would lead, how difficult it would be to adjudicate stands, and how many disqualifications would be called for on account of erroneous setting-up. I think, therefore, that before long the National Rose Society will have to take the matter up, for it is quite as important as that of "Too Much-alike Roses," on which I have received a large number of replies, and hope very soon to give the outcome of the letters which I have received.

My own judgment, which I humbly submit to Rose-growers and exhibitors is this: That there be as hitherto but two classes, Hybrid Perpetuals and Teas. In the former class I should allow all Roses to be exhibited that have any claim to that character of second blooming, whether they are hybrids of Teas, Bourbons, or any other blood; in fact those contained in the nurserymen's catalogues of antumnal Roses. If any of the Hybrid Teas are found worthy of this company they will no doubt be exhibited amongst them. But independently of anything else, it would be giving them a false status if they

were to be exhibited as a separate class and only had to compete with one another.

With regard to Teas, I am almost inclined to think that I should rigidly confine this class to Teas properly so called. "What!" some will exclaim, "exclude Noisettes? Shut out Maréchal Niel?" Well, yes. Maréchal Niel has so generally the post of honour assigned to him of being exhibited by himself that he may be left to take care of his own honour, and there are very few of the other Noisettes ever shown in a stand of Teas; and does not a large bloom of Maréchal Niel or a cluster of Céline Forestier destroy the evenness of a stand? Instead, however, of shutting them out altogether I would prefer giving them a place in my first division as autumnal Roses. I think the Teas are so especially lovely for their refinement that I personally dislike anything that interferes with this. Many persons rapturously look forward to crimson Teas. Let me confess that I do not indulge in the rapture. A great beauty to my mind in a Tea is the delicacy of colouring—the beautiful tints of salmon, peach, apricot, rose, yellow, white, and copper so marvellously mixed together, so delicate and refined, and this would be wanting in a stand where crimson was present. It is not the size and shape of Cheshunt Hybrid that alone make it out of place in a stand of Teas, but its colour also. The objection will, I have no doubt, he present to many minds; but then how much of sameness there must Yes, there is a sameness, but it is one of beauty; but with the variation of form that there is in the class and the wonderful mixture of colour no one, I think, will complain much of sameness who really loves a Bose.

Having set the ball rolling I hope that others will take it up, and that out of the multitude of counsellers there may come wisdom. - D., Deal.

KITCHEN GARDEN CROPS FOR 1880.

THE present is an excellent time to arrange the kitchen garden crops for 1880. The common plan of treating all ground alike and arranging the crops when it is time to put them in in spring is not to be recommended. In gardens where the soil is all the same this might pass, but unfortunately there are few gardens with a uniform good and deep soil, and therefore it is always best to arrange the crops to suit the quarters. Many soils which have never been trenched, but only surface-dug, will not produce good Parsnips, Carrots, or Beetroots. Trenching to the depth of 2 feet or more would frequently make a great difference to many crops, but at the same time a piece of ground which requires trenching must be studied. We once knew a gardener who went to a place where the garden had never been trenched, the only tillage done being to dig plenty of manure into the surface to the depth of not more than 10 inches. The new comer had all the garden trenched 2½ feet deep the first winter, and next season scarcely a vegetable would grow in the garden, as the subsoil which had been brought to the surface was so unsuitable, and it was some years before vegetables were produced in the same good condition as formerly.

Of course in such cases trenching will have its advantages in the end, only it should be studied at first, and to prevent the operation from interfering in any way with the supply only one piece or quarter should be done annually. Another good way is never to bring bad subsoil to the surface, but trench it down to the bottom as before, and cover it with good surface material. Some parts of the kitchen garden are good surface material. Some parts of the kindled garden are very stiff and sterile, but we are annually improving this by double digging and working large quantities of old vegetable refuse to the bottom. By this means in a few years we shall have a deep rich soil in which any vegetable will grow luxuriantly. In arranging the crops for next year Parmips, Carrots, Beet, and such roots must be in the deepest soil.

For many years the Carrots in our garden were poor and small. Last autumn about this time a good sprinkling of gas lime was thrown over a piece of ground and dug in. seed was sown on this piece in spring, and the results were most satisfactory. Now we are making ready another piece for next year. Next spring Parsnips will be sown on the piece from whence the Carrots have been taken, Onions will follow Celery. When the Celery is cleared the ground will only be dug up roughly. Before the Onions are sown a quantity of manure will be forked in the surface. After Celery a sprinkling of gas lime will be dug in to kill grubs, &c.

Any kind of lime is excellent for all old wormy or worn-out

soils, and gas lime might be more often used than it is, only it

must be used in small quantities, and placed in the ground some time before the crop—that is to say, dig the gas lime in now, and the ground will be in excellent order for any crop in the spring. At one time we dug all manure into the ground in autumn and winter, and this was the easiest plan, but now we do not, as a rule, turn any dung under the soil until just before the crop is to be planted, and we think this produces the best results.—A KITCHEN GARDENER.

CARNATIONS AND PICOTEES .- No. 11.

THE present season has been generally against Carnations and Picotees. From all quarters we hear that the young plants have no roots. I think that this rootless condition is owing to the parent plants starting into active root growth after the layering was done, the result being that the layers have continued to be nourished by the parent plants instead of producing roots. I find in many cases that the roots of the parent plants have hardly reached the sides of the pot. However, in high bleak situations I see no better plan than was adopted by an old grower who used to reside on one of our high Yorkshire hills. At a certain time he took off the layers, rooted or not: those not rooted he inserted thickly either under glass in a bed composed of soil from the pots or else replaced them in the large pots, and standing them in cold frames. After this the lights were placed over them and allowed to remain until spring, ventilating frequently by propping up the lights, but never removing them entirely. I have frequently obtained from him, in March, plants with a short bunch of roots half an inch long.

Those who have their plants firmly established in small pots will require to keep the lights propped up night and day in dry weather. As to the best position in which to place the frames, this will greatly depend on the shelter that may be afforded by trees, hedges, buildings, &c., as the more air is given to the plants the finer they will be. The aspect I have found the best is a south-eastern one, but then my situation is high, cold, and sunless generally in the winter months. In clear warm situations I should recommend a north, north-east, or north-west aspect. Remove all dead or decayed foliage, water sparingly, and take care to prevent the water from penetrating into the heart of the plants.

Those who have a pit or cool house may continue placing in them such plants as may be required for next year. Those who have not the convenience of a pit or cold house may plunge the pots up to the rims in cocoa-nut fibre refuse or ashes, keeping the lights of the frame moderately close so as to encourage root-action.

Plants in beds should be frequently looked over. Any which may be loosened or thrown out of the soil should be placed firmly in the soil. Tall-growing varieties should be tied up to stakes to prevent them from being broken by the wind. If the weather continues fine examine the plants closely for slugs. If the weather proves wet and dull any plants that may look sickly should be covered with a bellglass. Empty all pots as soon as possible after the layers are taken off. The soil which has been used last season can be used again in the proportion of half old soil and half new. The reason I recommend the pots to be emptied at once is, that in late cold situations like mine the pots frequently break if the soil is allowed to become frozen in them. Any stems which may have pods of seed unripened on them should be cut off and placed in water in a dry room, where they can remain until the pods turn yellow, when they may be cut off and allowed to dry in the ordinary way.—GEO. RUDD.

NAPHTHA FOR SCALE.

REPLYING to "W. T. P. H." the Rev. W. F. Radclyffe writes as follows:—"The naphtha used was liquid. I did not measure the quantity, but simply poured some into the watering pots, and having stirred it used the syringe. The best remedy for brown scale, as suggested to me by the late lamented Mr. Rivers, is methylated spirits laid on the scale with a camelhair brush. As to Ferns I know nothing; the same may be said of Chrysanthemums. I am not much in favour of violent remedies; sometimes the remedy is worse than the disease. If the querist has only a few plants, perhaps sponging with cold water or dipping the plants into a tub of water would cure the evil complained of. I have only tried the naphtha and water on Peach and Nectarine trees. I believe cold water would if constantly applied keep down our enemies. When trees are syringed the operator should not stand in the front of

the trees, as the enemy is usually under the leaf, but stand and syringe sideways. Scale on Peaches and Nectarines are on the points of the shoots, and are usually accompanied by ants. This year I have seen neither scale nor ants, only one red spider, and no mildew."

AGAINST HARD PRUNING.

"Nor so bad after all," was my sigh of relief after reading Mr. William Taylor's long-promised critique on my article on the summer pruning of fruit trees, which appeared in the number he has quoted—namely, of July 31st. Four months is a long time to wait for a verdict; but being conscious that I had not seriously sinned against the tenets of good practice in fruit culture, I was not troubled by the thought that the sentence would be a severe one, and it is even more mild than I anticipated.

The importance of the subject in hand is so great and withal so seasonable, and the tone of your correspondent's letter is so excellent, that it is, I presume, for those reasons his communication was accorded the post of honour in the Journal, rather than as editorial sanction being given to all that he has said in relation to the subject. Glad am I that the merit of the paper has been thus recognised, for it is one that may be read with advantage by all controversialists, not excepting, if I may be permitted to say so, some of our ecclesiastical friends.

While there are sentences in Mr. Taylor's article on page

While there are sentences in Mr. Taylor's article on page 399, the correctness of which I shall certainly question, there are only about two words to which I really object. I am described as a "formidable opponent." Now I disclaim being an opponent at all; and as to being "formidable," I cannot accept a compliment, however honestly given, that I feel is not merited. I had rather be regarded as an assistant to Mr. Taylor than as an opponent of him. Our objects are identical—namely, seeking to promote and improve the culture of hardy fruits; and there is far less difference in our views on attaining the desired end than is shown on the face of the article quoted. As to either one or the other getting the best of the argument that is, and I say it with all the emphasis possible, to me personally a very secondary matter.

Although there are one or two which I regard as vulnerable

Although there are one or two which I regard as vulnerable points in Mr. Taylor's "case," rather than seising on them at the outset I prefer first to controvert his premisses. As all readers of the Journal must admit, your correspondent's perceptive faculties are the reverse of dull, yet he has quite missed the real point and scope of my article which he has so skifally dissected. I daresay he has read that article more than once, yet it is just possible that he made his promise of "attack" rather prematurely. I ask him to read it again, and he will, I think, see with other readers that the real nature of the question propounded is not an advocacy of excessive pruning as such, nor of pigmy versus orchard fruit trees, but of summer versus winter pruning of fruit trees generally, not even excepting, for they were specially mentioned, of wall trees. Further, the mode of procedure that I advised, and the soundness of which I am as conscious as ever, as I am fortified with results that have proved it sound, was made under special circumstances—namely after three, or in many places four, and in some five, unfruitful seasons, and during an abnormally dull and wet summer.

"WILTSHIRE RECTOR" recognised my point and object in a reference to my letter, and possibly, as I know some others advocated. In my communication I plainly stated that "Iam not an advocate of an extreme course of summer pinching and pruning of all trees under all circumstances." Is not that clear enough? Then take the next lines—"I do not adopt the practice of crippling the growth of young trees, and therefore an unable to rejoice with Mr. Peach on the conspicuous precocity of his young three-year-olds." That is to my mind more condemnatory than laudatory of "pigmy" trees. I stated that "one of my tenets on the culture of fruit trees is that a tree should be allowed to attain a size capable of maturing the fruit without any great strain on the tree's resources before it is encouraged to produce a crowded crop." Is that "horticultural millinery?" Whether it is or not, I nail my colours to the mast and ask my friend to fire away at them. I went further, and asserted that "if a tree will bear without any great amount of pruning I can very contentedly let it alone." Is that and occay of "hard pruning?" Your correspondent quotes my remark that there were in the last week in July "thousands of so-called pyramid and bush fruit trees into the centres of which the

light can find no entrance, and leaves and spurs are in semidarkness "-quotes it to confirm it. He then observes that we differ about the causes. I suspect he there makes a mistake; and I am certain in the next line he is in error when he states his opponent (myself) "says they are pruned too much." When and where have I said it? What I said was this, that the absence of fruit for four or five years had caused many trees to grow exuberantly, and the growth made in semi-dark-ness, as admitted by Mr. Taylor, was essentially unfruitful in its nature. He equally with myself admits the evil; but there is this difference between us, that I suggest a remedy, while he appears to prefer to let the evil grow.

Pruning an exuberant tree, says your correspondent (who reams winter pruning), affords only temporary relief, like cutting one's corn and still wearing the small shoe which caused it. If the foot had been allowed to expand the corn probably would not have come." Very true. The force of that sentence lies in the "if"—a very awkward little word, but sometimes useful. I may with equal fairness say that "if" the trees had been fruitful instead of barren during the past few years the evils of overcrowding and succulent unfruitful growth would not have been present. But they actually existed. If a soldier has a limb shattered in action do the surgeons sit down and argue the point in this manner?--If the man had stayed at home this would not have happened; and if there had been no war the case would not have been brought before us. No, the evil is before them an admitted fact, and instead of discussing the cause they promptly apply the best remedy in their power, even if that remedy is amputation.

I am thoroughly convinced of the great evils of severe winter pruning when the object desired is to produce healthy, matured, fruitful wood. I know by much experience that the knife improperly employed is the prime cause of overcrowded fruit trees, and I have for a long time ceased to use it to any great extent on trees during their season of rest; but thinning out the branches of overcrowded young fruit trees towards the end of summer is quite another thing. That practice rightly performed is sound practice, and during a season like the present has most certainly effected a great improvement in the condition of many fruit trees. It is well if the trees required no such aid; but as Mr. Taylor knows very well, and has admitted, many trees were in a very different condition two or three months ago, and he leaves them by asking, "Whose fault is it?" Well, never mind whose fault it is. The trees required assistance, and instead of seeking to fix the fault on anyone—a thankless, and under the circumstances an impossible task—I endeavoured to point out a remedy, and your correspondent has certainly not convinced me that I was wrong in

doing so or that I suggested a wrong mode of procedure.

I am a great admirer of standard Apple trees on the Crab stock. They are the most useful of all trees for supplying the markets with fruit, but I cannot condemn dwarf trees on freegrowing Paradise stocks. I do not mean stunted pigmies, but trees such as a short time ago I could have shown to Mr. Taylor with two bushels of fruit on each, while the orchard trees, young, middle-aged, and old, not a hundred yards from them were barren. I will not now incite controversy by sug-gesting what I think is a reason for the difference, but simply state the fact as showing that I at least have some reason for saying a good word for bush Apple trees pruned in summer but not in winter.

Many readers had not the privilege of seeing the finest hardy fruit show of the year at Hereford. I presume that fruit from dwarf-grown and regularly pruned Apple trees was staged against fruit from unpruned standards. Which won? The answer to that question shall be my answer to Mr. Taylor's remark relative to that phase of the subject mentioned in his letter.

I should like to refer more fully than I am able just now to the mode recommended for planting standard Apple trees on meadow land. I know there is rich alluvial land on which the plan will answer very well, but I also know equally well that there are miles of country where the soil is shallow and the rainfall low, where the prescribed mode of planting would not answer at all. The result would be this, the knife being thrown away as advised-that many of the trees would form fruit buds from the base of the extremity of the shoots, the terminal bud also being a fruit bud. What then? Free-growing healthy trees capable of producing serviceable crops—no, but trees, and I have seen many of them, that can only be described as pigmies on stilta.

I have more to say on this question, which is an important one, but cannot say it now, and I daresay my able coadjutor will give me an opportunity of returning to the subject.-A NORTHERN GARDENER.

A GERMAN ELECTION OF ROSES.

THE object of this election is to reduce the four or five thousand varieties of Roses at present grown in our gardens to a limited number of really valuable varieties, to publish their names, and to recommend their cultivation. All answers to the questions given below should be sent in during November and December, 1879, post free to my address, and be accompanied by the distinctly written signature and full address of the sender, in order that I may communicate the result to him. Reports reaching me after the end of December would be too late to be of any use. To each variety should be added if possible the name of the raiser and the year of its intro-duction. The required number of varieties should on no account be exceeded, and it is particularly requested that correspondents will name Roses of sterling merit only. To further this undertaking I earnestly solicit the horticultural press to publish lists of questions in their columns, the honorary secretaries of all the horticultural associations to submit them to the members, and all who are interested in the cultivation of the queen of flowers to assist as much as possible. The printed result of this election of Roses will be communicated gratis and post free to all the horticultural papers and all correspondents who have taken part, and to those only, in order not to increase unnecessarily the expenses of this undertaking, which are borne by the Wittstock Horticultural and Agricultural Society.

LIST OF QUESTIONS.

Name and occupation of the correspondent, address, and date. I.—Which are the three best Roses as regards form, substance, habit, and scent in each of the following colours ?-A, Hybrid habit, and scent in each of the following colours —A, Hybrid Perpetuals and Bourbon Roses—a, pure white; b, tinted white (pale flesh-colour); c, pale pink or light rosy; d, bright pink or deep rosy; e, carmine; f, scarlet and vermilion; g, purple and crimson; h, dark marcon or brownish; i, violet; h, striped. B, Tea-scented Roses and Noisettes—l, pure white or slightly tinged (three Roses); m, pink (rosy); n, tinted pink; c, pale and bright yellow; p, yellow tinted.

II.—Which are the three most beautiful Moss Roses?

III.—Which five varieties of Roses are the greatest favourites and the most generally cultivated in the district of the corre-

IV,-Which five Boses are distinguished by-a, uninterrupted

blooming; b, superior scent; c, hardiness?

V.—Which five Hybrid Perpetuals are the freest bloomers—

a, for the summer; b, for the autumn?

VI.—Which are the ten best Roses for forcing?

VII.—Which five varieties are best adapted for cultivation

in rooms?

VIII.—Which are the three most beautiful pillar Roses?

IX.—Which ten novelties from 1873 till 1878 are of such remarkable beauty that their cultivation and distribution can be recommended without the slightest hesitation?

X.—Which are the best ten English-raised Roses? I refer to such Roses as have been raised by Messrs. W. Paul, G. Paul, Cranston, Keynes, Turner, and Bennett, all of whom have raised Roses of the first quality, to which even French raisers and rosarians like Messrs. Guillot fils, A. Levet, Jean Sialey, S. Cochet, Camille Bernardin, &c., could not refuse admiration. The English Rose-raising is fully equal to French and more honest, for the value of a new Rose is there fixed not by the raiser but by the National Rose Society in public competition at the Rose shows.—FRIEDRICH SCHNEIDER, President of the Horticultural and Agricultural Society, Wittstock, Germany.

PRIZE CARDS AT EXHIBITIONS.

THE horticultural shows for the past year are now rapidly drawing to a close, and while we consider the disadvantages exhibitors have had to contend with during the present sunless and cold season, we may safely venture to say the majority of exhibitions have not been less attractive than in past years; some have even considerably improved. The earlier shows of the year were certainly short of fruit, owing to the lateness of the season and the want of sunshine; the quality, too, was not quite equal to that of previous years, yet other exhibits at the same shows were wonderfully attractive. Flowering plants on the whole this year were good, and could not well be surpassed in the most favourable of seasons. But it is not altogether upon the exhibits of past shows that we are writing, as we wish to refer to the different systems of placing prize cards on the various exhibits after the judges' decisions. Each society appears to have its own system, and some we must confess are very imperfect. Not unfrequently have we seen many blunders occasioned by the method of carrying out such work and the delay in affixing the prize cards. In some cases the judges are followed and the cards written after their decision, in others they are all written in the secretary's tent and then conveyed to the exhibits. These systems not only entail a large amount of labour on the day of the show, but cause much delay and frequently annoyance. At several shows we have attended this year we have seen some very unsatisfactory systems prac-tised, and the public admitted before half the cards were up. This is not only disappointing to the public who are anxious to see who have been the successful exhibitors, but it makes

the reporter's work hard and annoying.

There is abundance of time now for societies to consider these matters and make better arrangements for another season. The admirable system adopted at South Kensington is one that should commend itself to every society. It is free from the disadvantages above named, and when the judges have accomplished their work the whole is done, the prize cards up, and reporters able to follow and keep up with the judges. The prize cards should be written or printed previous to the show for every entry, and the class number and the number of each exhibitor should be placed on the back for the guidance of the judges. After staging, the card should be left the reverse side up, so that the exhibitor's number and class number can be seen by the judges. An assistant must follow each set of judges with small printed strips of first, second, and third prize, which should be gummed on the prize card. By following this system, and each set of judges having a copy of the "Field Duplicate Judging Book," which requires but little preparing and is very cheap, the numbers of the prisewinners are entered in as they proceed. As each class is finished the alip from the "Judging Book" should be torn off and sent to the secretary's tent for his books to be made up. Thus, when the judging is done all is done: no mistake need be made, and no annoyance occasioned.—W. BARDNEY.

ACANTHACEOUS PLANTS FOR WINTER FLOWERING.—No. 5. HYPORSTES.

THIS genus contains a great number of species, the greater portion of which are not deserving cultivation by the amateur. Those here quoted, however, are striking exceptions to the rule. They are nearly allied to Justicia and Eranthemum, the calyxive like bracteate involucre enveloping the flowers being perhaps one of the most distinguishing features. Culture the same as Eranthemum.

Hypostes sanguinolonta.—This is a most desirable species. The extreme beauty of its variegation renders it a conspicuous object in the plant stove. Being first distributed under the object in the plant stove. Design instructed under the name of Eranthemum sanguinolentum it may probably be more familiar to our readers by that appellation. Stems four-angled, attaining a height of about 12 or 18 inches, very sparingly branched. Leaves opposite, oblong obtuse, alightly pubescent on both sides, some 3 or 4 inches long and nearly inches wide, deep green, with a broad purple band traversing each vein, so that when not in flower it is extremely correspond to the problem of the statements. ornamental. Panicle terminal, branched, and erect. Corolla twisted; tube slender; limb soft rosy-purple; throat white, spotted with dark purple. Native of Madagascar.

H. aristata.—A handsome species when in flower. In habit

it assumes the proportions of a dwarf shrub, attaining a height of 3 or more feet. Stems almost terete, but sometimes bluntly four-angled. Leaves opposite, ovate, acuminate, slightly pu-bescent, some 3 inches long, and dark green. Flowers axillary, forming crowded spikes on all the branches. Corolla tube slender, rosy purple; lobes spreading and recurved, deep purple; the upper lobe striped and spotted. It blooms in January and February. Natal.

The species here introduced is, we believe, the only member of the genus in cultivation, but this is perhaps amongst the very finest member of the order yet introduced. It may be kept a second year with advantage. Pot in peat and loam, with a little sand added.

Anoylogyne longiflora.—A smooth undershrub of compact habit. Stems four-angled. Leaves ovate-oblong in shape, some 9 inches long, and tapering to a point, bright green above, paler beneath. Flowers arranged in a long terminal drooping branched panicle; they are cylindrical and tubular, enlarging upwards, about 2 inches long, and rich bright purple in colour. It blooms during March and April. Native of Guayaquil.

BRILLANTAISIA.

A genus containing but few species, the one here quoted being very handsome, and, as far as we are aware, the only one in cultivation. It is a rather coarse-growing plant, and should have a heavier soil than we have recommended for the majority of these plants. It should be cut back after flowering, and grown a second year.

Brillantaisia ovarionsis.—This is a robust plant, having somewhat the appearance of a large-growing Salvia. Stems fourangled, pubescent. Leaves ovate-cordate, upon long petioles, coarsely toothed at the margin, and deep green. Flowers arranged in large terminal panicles. Corolla tube short; limb large and spreading; the lower lobes being deep violet blue, which renders it very attractive. Native of West Africa.

MACKAYA.

The distinctive characters of this genus are not known to us. According to Lindley Mackaya belongs to the order Lossaces, but the plant here introduced to our readers' notice is certainly a member of the Acanthacese, and has been dedicated to a well-known botanist, author of "Flora Hibernica," &c. It requires a moderate heat only, with an abundant supply of water both to the roots and from the syringe. Pot in loam, peat, and leaf mould, with a little sand added. It deserves to be cut back after flowering and grown a second year.

Mackaya bella.—A tall-growing twiggy shrub. Leaves opposite, oblong ovate, smooth, coarsely toothed at the margins, some 4 inches long, bright green above, paler beneath. Racemes terminal, much longer than the leaves. Flowers standing all one way, or secund, tubular, spreading upwards into a broad, campanulate, five-lobed limb; colour soft pale lilac, beautifully netted with purple. It is a truly charming plant, blooming during April and May. Native of Natal, by the River Tougat. GOLDFUSSIA.

This family contains several very pretty species well deserving a place in the stove for the beauty and abundance of their spring-struck plants every year in preference to the old mes. The chief characteristics of the genus are thus defined:—"The flowers have two deciduous bracts, and are arranged in a head or spike, an unequally five-parted calyx, a funnel-shaped corolla with an unequally five-cleft limb, four didynamous included stamens with nodding anthers, and a subulate irritable stigma."

Gold/ussic isophylla.—A dwarf, compact, much-branched rub. Stems four-angled, somewhat tumid at the nodes. Leaves opposite, narrowly lanceolate, acute, some 3 inches long, scarcely a quarter of an inch wide, deep green above, pale beneath. Flowers produced in small heads upon the spex of every branch, funnel-shaped, about 1½ inch long; color lilac. It blooms in September and October, continuing several weeks in perfection. Native of the East Indies.

G. Thomsoni.—This is a somewhat looser-growing plant than the preceding, more sparingly branched; it is nevertheless a most desirable species. Leaves opposite, ovate-lanceolate, acuminate, slightly serrate at the margins; upper leaves sessile; lower petiolate, some 3 inches long, bright green above, tinged with dull purple beneath. Flowers produced in small heads on the apex of all the branches, tubular, spreading into a large funnel-shaped corolla of a deep violet blue. Native of Sikkim.

VEGETABLES AT MESSRS. CARTER'S ROOT SHOW.

In addition to the numerous classes provided for roots at the above Show, of which particulars will be found in another portion of the Journal, four classes were appropriated to collections of vegetables, Potatoes, and Onions, from gentlemen's gardener, farmers, and amateurs. The principal class was that for twelve dishes of vegetables, and there Mr. Iggulden, gardener to R. W. Wingfield Baker, Esq., was awarded the premier position with remarkably handsome even dishes including, in extra fine condiremarkably handsome even dishes, including, in extra fine condition, Carter's Incomparable Crimson Celery, Snowfiske Potatoes, Trophy Tomatoes, and Carter's Perfection of Beets. The second prize was adjudged to Mr. R. Phillips, gardener to Captain Jackson, who also exhibited fine dishes, the following being of unusual

merit—Carter's Perfection Sprouts, Carentane Leeks, and Acme Tomatoes. W. S. Baldwin, Raq., occupied the third place with fair specimens, Carter's St. Osyth Beet and Ayton Castle Leeks being well shown. For the best eight dishes of Potatoes, nine being well shown. For the best eight dishes of Potatoes, nine tubers of each, there were eleven entries, the competition being close and good. The chief prize was obtained by C. W. Howard, Esq., for excellent examples of Grampian, Snowflake, Brownell's Beauty, Schoolmaster, Carter's Main Crop, and International. The second and third prizes were awarded to J. Creed, Esq., and Mr. J. Clark, gardener to Lord Hastings, both of whom exhibited highly creditable collections. J. Creed, Esq., staged the best dish of Carter's Improved Magnum Bonum Potato, Mr. W. Iggulden and C. W. Howard, Esq., closely following in the order named. Fifteen exhibitors appeared in the class for twelve Onions of any variety, and the premier award went to J. Thorne, Esq., for neat and even samples, Mr. Phillips staging a collection but slightly and even samples, Mr. Phillips staging a collection but slightly inferior in merit.

THE DEVON ROSERY.

MESSRS. CURTIS, SANDFORD, & Co. are well known as large and successful cultivators of the Rose. A November trip into Cornwall and South Devon gave me an opportunity of visiting the birthplace of sweet and beautiful Devoniensis. The day after my arrival at Torquay I went round these nurseries with Mr. Sandford. His men were very busy lifting Roses, orders

being very plentiful this season.

I noticed a fine breadth of forty thousand standards, not so good as in some previous years, but then last winter's frost was felt at Torquay as well as at Monckton Wyld. The dwarfs looked clean and healthy, especially those on the Celine stock: there were from ten to twelve thousand of these, including three thousand Gloire de Dijon. The demand for Roses on the Celine is greater than the supply. Mr. Sandford says he cannot do at all with the seedling Briar, and from what I saw of the plants on this stock something was clearly amiss, neither does he like the Briar cutting—not fibrous roots enough.

The soil is a lightish and somewhat gritty marl—not a bad soil; the climate everybody knows. No mulching or protection required in winter, although, as I said before, last winter's sting was felt. The nursery slopes on either side down to a little stream, which is convenient for summer waterings, but which would play havoc among my Rose trees in East Worcestershire during any ordinary winter. But at Torquay the only trouble from frost comes in spring when everything has well

started into growth.

If all Roses were as popular as the Duke of Edinburgh the nurserymen would have a busy time of it. I saw here eight hundred of His Royal Highness on Manetti stocks in one piece. The grafting of Roses had commenced; there were eighteen

thousand stocks all in pots ready to be operated upon.

Let me recommend visitors to Torquay to have a good peep at the Devon Roseries, any time from middle of May to middle of November, and they will be rewarded beyond anticipation.

-J. A. ₩.

CHRYSANTHEMUM AND FRUIT SHOWS. SHEEFIRI.D

PERHAPS there are more Chrysenthemum shows in Sheffield than in any other town in the kingdom—private venture shows in-stituted by enterprising publicans, who take advantage of the attractions of the flowers to fill their houses with the "fancy." Fanciers of garden produce are numerous, and shows of some kind are held during almost every week in the year, the majority of them on Sundays. On Sunday last we were informed that probably as many as twenty Chrysanthemum shows were held in the town and environs—stands of blooms exhibited by anyone and from anywhere; blooms grown, or purchased, or begged by exhibitors, whose entrance fees added to the sums given by the landlords of the "houses" constitute the prizes. The Exhibition under notice is, however, of a very different character. It is the second autumn Show promoted by the Sheffield and Hallamshire Gardeners' Improvement Society—a Society that is receiving the support it deserves, for we are glad to see that it has as President the Rev. Canon Blakeney, D.D., Vicar of Sheffield, and such influential Vice-Presidents as Sir John Brown; F. T. Mappin, H. Wilson, W. P. Milner, Mark Firth, H. E. Watson, J. E. Caller, B. P. Broomhead, and D. Ward, Esqrs.

All the privace ware of an honorarchy and a such a such as a support of an honorarchy and a such as a such as a support of an honorarchy and a such as a such as a support of an honorarchy and a such as a support of an honorarchy and a such as a support of an honorarchy and a such as a support of an honorarchy and a such as a support of an honorarchy and a such as a support of an honorarchy and a such as a support of an honorarchy and a such as a support of a support of an honorarchy and a such as a support of an honorarchy and a such as a support of an honorarchy and a such as a support of a

All the prizes were of an honorary character, no money, cups, nor medals being given to local exhibitors, but only certificates of merit representative of first, second, and third prizes in the various classes; yet a silver cup with other prizes were provided in the open class for twenty-four incurved Chrysanthemums, the object being to have blooms of a high standard of excellence from other districts. In this open class Mr. Tunnington, gardener to C. McIver, Req., Calderstone, Liverpool, and Mr. Faulkner, gar-

dener to J. R. Leyland, Esq., Woolton Hall, Liverpool, competed, and astonished the gardeners of Sheffield and visitors to the Show by the size and magnificence of their blooms. Mr. Tunnington won the size and magnificence of their blooms. Mr. Tunnington won the cup by six points with the finest stand we have seen this year, the majority of the blooms being fine in size, form, solidity, and general finish. Novelty, Prince Alfred, Empress of India, Mr. How, Golden Empress, Queen of England, Princess of Wales, Mrs. Heale, Beauty, Cherub, White Venus, and Isabella Bott, all high-class blooms; and the others, Hero of Stoke Newington, Sir Stafford Carey, Jardin des Plantes, Bronze Jardin des Plantes, Barham, Prince of Wales, Princess of Teck, Venus, Eve, Lady Hardinge, Mrs. G. Rundle, and Princess Beatrice were in admirable condition. Mr. Faulkner had one or two blooms perhaps superior to Mr. Tunnington's notably Empress of India and the superior to Mr. Tunnington's, notably Empress of India and the golden variety; and especially good, but not large, was Beauty, and the majority were of great merit and very fresh, but some too and the majority were of great merit and very fresh, but some too small—in fact they were not quite at their best, while Mr. Tunnington's as a whole were in the full zenith of beauty. Mr. Walker, gardener to B. P. Broomhead, Esq., was the premier local exhibitor, and secured third honours in the open class. Mr. Marsden, gardener to J. R. Cutler, Esq., had the chief prize in the local class of twenty-four blooms with small but extremely neat examples. Mr. Walker second, and Mr. Foggin third with very small flowers placed on very large discs of violet paper. Most of the blooms were shown on white paper, including Mr. Tunnington's, but not Mr. Faulkner's nor Mr. Walker's. It is not necessary to refer to the minor classes, nor to the plants, which were sary to refer to the minor classes, nor to the plants, which were generally inferior.

generally inferior.

Primulas were a prominent feature of the Exhibition, splendidly grown plants being staged by Messrs. Mareden, Walker, and Stimpson, gardener to J. Cravan, Esq. Mr. Woodcock, gardener to F. W. Mappin, Esq., was well in advance of other competitors with groups of plants and Ferns; with good plants tastefully arranged Mr. Cozens, gardener to W. Hutchinson, Esq., and Mr. Walker exhibited well and successfully in these classes. For hardy Ferns Mr. Esdon was first with a choice collection.

Of the fruit stead only the Grapes and a few Pesrs staged by

hardy Ferns Mr. Radon was first with a choice collection.

Of the fruit staged, only the Grapes and a few Pears staged by
Mr. Hall, gardener to Mark Firth, Req., were superior. The exhibitor named secured the chief prizes for Grapes with fine examples
of Black Alicante and for a collection of fruit. But the finest fruit contribution in the Show was the collection of Grapes not for competition from Mr. Abbott, gardener to C. H. Firth, Req., including splendid bunches of Mrs. Pearson, Golden Queen, Alicante, Madresfield Court, Muscat of Alexandria, and Frankenthal.

cante, Madresfield Court, Muscat of Alexandria, and Frankenthal.

Mr. Abbott also exhibited his fine Pea Hallamshire Hero, referred to on page \$44, and which was awarded a first-class certificate.

Mr. Clements, gardener to H. Wilson, Baq., exhibited plants, which were highly commended for superior culture, of Nepenthes, Maranta Massangeana, and Sonerilas; and Messrs. Fisher, Holmes, and Sibald B. Crossland, and Mr. Udale, gardener to H. Watson, Req., were highly commended for large, well cultivated, and excellently arranged groups of flowering and fine-foliaged plants that contributed greatly to the effect of the Exhibition.

The Exhibition was held in the Cutlers' Hall on Monday and Tuesday last, and was well attended; and the officials, including Mr. Woodcock the industrious Secretary, worked hard to render it successful, but with a better system much labour might be saved and more satisfactory results produced in affixing the prize cards and conducting the general routine duties of the Show. The Sheffield Chrysanthemum Show is yet in its infancy, but now the sheffield Chrysanthemum Show is yet in its infancy, but now the members have seen what can be done by high culture in producing grand blooms they are certain to profit by the lesson; and if the Society receives the support that it certainly merits, shows worthy of the great, busy, and wealthy town will be produced in the future.

SOUTHAMPTON.

The second Exhibition of Chrysanthemums, fruit, vegetables, and cage birds was held in the Victoria Skating Rink on the 18th and 19th inst. The Committee were most fortunate in procuring

and 19th inst. The Committee were most fortunate in procuring such an admirable structure, for the building was large, elegant, and light, the greater portion of the roof being constructed of glass. The exhibits of horticultural produce were arranged on tables extending the whole length of the building, while the cage birds occupied the other portion. A few miscellaneous plants were placed around the sides and columns of the hall in a very tasteful manner. The schedule comprised forty-one classes, the first sixteen of which were allotted to Chrysanthemums, seven being open to all; two were for nurserymen only, and the remaining portion for gardeners and amateurs. In the whole of the classes there was very keen competition, and among the fruit and vegetable collections were some of the extremely good specimens. Following in the order of the schedule, in Class 1 the subscription challenge prize of £5, open to all England, was offered for twentyconowing in the order of the schedule, in Class 1 the subscription challenge prize of £5, open to all England, was offered for twenty-four cut blooms of Chrysanthemums, distinct varieties, for which there were six competitors. The first prize was well won by Mr. Moorman, gardener to Miss Christy, Coombe Bank, Kingston-on-Thames, with a collection of large and handsome flowers, consisting of eight Japanese and sixteen incurved varieties. The back row of Mr. Moorman's stands were all Japanese—a very pleasing arrangement. The back varieties were M. Ardina The best varieties were M. Ardène pleasing arrangement.

(very fine), Elaine, Fleur Parfait, Fair Maid of Guernsey (good), Bouquet Fait, Madame Lemoine, Beverley, Mr. Bunn, Beethoven, Ledy Hardinge, Mrs. Dixon, Prince of Wales, Golden Empress of India, Mr. G. Glenny, White Venus, and Novelty (very fine). Measrs. Jackson & Son were second with the following among others:—Fair Maid of Guernsey, James Salter, Elaine, Bouquet Fait, Red Dragon, Prince of Wales, Mr. G. Glenny, Gloire de Toulouse, and Golden Beverley. Mr. Wills, gardener to Mrs. Pearce, The Firs, Basectt, occupied the third place; and Mr. C. Dear, St. Andrew's Lodge, Southsea, the fourth. For the most effective group of Chrysanthemums arranged with Palms, Ferns, and other foliage plants Mr. Wills was well to the front with a tastefully arranged group, araongst which were a fine Davallia Mooreans, some very well-coloured Crotons and Dracesnas. Mr. J. Amys, gardener to the Hoa. Mrs. E. C. Yorke, Netley Fort, gained the second honeurs. In the class for the best collection of Chrysanthemums, arranged in a space 8 feet by 5, Mr. Allen, gardener to themums, arranged in a space 8 feet by 5, Mr. Allen, gardener to J. Bailey, Esq., was deservedly awarded the premier prize for a group displaying much taste in arrangement. Mr. E. Wills was a good second, but his collection was somewhat crowded. Prizes were offered for six Pompons, but these were poor. Mr. Thomas, gasdener to R. R. Scott, Esq., was awarded the first prize for a

gardener to h. h. hours, heat, was awarden one mass passe for a single specimen plant.

For twelve out blooms, incurved, Mr. Moorman was a good first, Mr. Wills second, and Mr. Allen third. There were seven collections staged. For twelve Japanese there were only two collections, Mr. Moorman and Mr. Wills being awarded first and second honours respectively. The plants and cut blooms in the nurseryhonours respectively. The plants and cut blooms in the nurserymen's classes were very poor. For twelve plants, not less than
six varieties, Mr. Thomas was awarded the first prize for large,
loose, and untrained plants, but exhibiting some very good quality
flowers of the "Randle" type. Mr. Amys was placed second with
better trained plants, but the flowers were not quite so good. For
twenty-four cut blooms in the gardeners' class there were several
cellections staged, Mr. Wills outdistancing all other local growers;

"Mr. When counted the accord write and Mr. West surfaces to Mr. Thomas secured the second prize; and Mr. West, gardener to

Mr. Thomas secured the second prize; and Mr. West, gardener to J. R. Wigram, Esq., the third place.

Table decorations were tastefully arranged by Miss Fraser, Mrs. Kingsbury, and Miss Chamberlain, who were first, second, and third respectively. Several meritorious groups of miscellaneous plants, arranged in a space 10 feet by 7, were staged both by gardeners and nurserymen. The best in the gardeners' class came from Mr. Wills, and contained fine coloured plants of Orotou undulatum and C. majesticum, good Marantas, Dracesnas, Rucharises, nicely flowered Oppripediums, Palms, &c., the outer edging being composed of small Ferns, Panieum, and Isolepis. This was a very effective group. Mr. J. Amys occupied the second place, and had amongst his plants some good specimens of Schrzostylis coccines. Schizostylis coccines.

Schizotylis coccines.

FRUIT.—This was, as we have already remarked, extensively shown. Some grand examples of Grapes were contributed by Mr. Johnstone, gardener to the Marchioness of Camden, Bayham Abbey, Kent. Mr. Johnstone was awarded the first prize for the heaviest bunch of Grapes (Syrian), a large bunch, and well finished. He was also first with two bunches of black, and third with white Grapes. Mr. Crump, gardener to H. Harris, Req., Steventon Manor, Micheldever, and Mr. A. D. Christie, gardener to H. Woods, Beq., were also very successful prizetakers for Grapes. The last-named obtained the first prize for white Grapes (Bowood Muscat) of a real amber colour. Apples, Pears, vegetables, berried plants, Primulas, &c., were all good.

We congratulate the Secretary, Mr. C. S. Fuidge, who, with the hearty co-operation of Capt. Gibbs and a few others of the Excentive, so ably carried out the arrangements of the Show. The "Field Judging Books" were used with great advantage here; and the system adopted throughout, even to the placing of

there; and the system adopted throughout, even to the placing of the prize cards, is to be commended, and is worthy of imitation in other societies.

SHREWSBURY.

The second fruit and Chrysanthemum Show of this Society was held in the Music Hall on Thursday, November 20th. The show of fruit was an excellent one; the competition was very close, especially among the Grapes. The Chrysanthenums were numerous and good. The Pompons, however, would have been better in another week or two.

smother week or two.

Specimen Chrysanthemams were well shown. For nine large-flowering varieties Mr. Farrant, gardener to Mrs. Juxen, Shrewsbury, obtained the premier award with very fine plants of Empress of India, George Glenny, Golden Beverley, Mrs. Dixon, Ledy Margaret, &c. These were unquestionably the best plants in the Show. Mr. Farrant was also first with six standard large-flowering plants, well flowered and trained. Mr. Thomas, gardener to B. Burd, Esq., was first with six standard Pompons, very good plants well grown. Meesrs. Oldroyd & Son, nurserymen, and Mr. Milner were placed equal first for six well-grown Pompons.

The cut blooms were excellent, especially those shown by Mr.

The cut blooms were excellent, especially those shown by Mr. Marrender, who was placed first with twenty-four (open to all England), the best amongst which were Golden Empress, Elaine, George Gleany, Alfred Salter, White Beverley, and Mrs. George Rundle. Mr. Milner was second with small but well formed blooms, There was good competition for six Primulas, and some very good plants were staged. Mr. J. Jones, Coton Hill Nursery, was first for six Cyclamens. He also exhibited, not for competition, one ball and two bridal bouquets in his usual style, which attracted much attention.

much attention.

Fruit was particularly well shown. In the class fer three bunches of black Grapes open to all England, Mr. McLean, gardener to Lady Louise Cotes, Pitchford, was first with good bunches of Black Alicante; Mr. Williams, gardener to Rev. W. C. Kynaston, Hardwick, was a capital second with very even and well-coloured bunches of the same variety. The Judges must have had no light difficulty in deciding between these two rivals. Mr. Boddy, gardener to Viscount Boyne, was first with three splendid bunches of Muscat of Alexandria, and Mr. Purser, gardener to J. Watson, Eq., Berwick, followed. For the best collection of Grapes, not less than four varieties, Mr. Boddy was again first with good bunches of Royal Vineyard, Muscat of Alexandria, Lady Downe's, and Black Alicante; Mr. Kite, gardener to A. Maw, Esq., was a good second, and Mr. Pearson, gardener to Lord Berwick, third. Not less than 140 dishes of good Pears were staged, and about the same number of Apples, Messrs. Pearson and Lambest taking the chief prizes. the chief prizes.

GRAVESEND.

The annual Exhibition of this Society, held at the Milton Hall on the 19th and 20th inst., was fully equal to that of last year, and as usual reflecting much credit on all concerned. Mr. Phillips, gardener to Captain Jackson, Meopham, was the most successful exhibitor, being placed first in nearly all the plant classes. His four dwarf-trained specimens of Mrs. Dixon, Mrs. G. Rundle, Mrs. Sharpe, and Gloria Mundi in the class for large-flowering varieties were particularly good. The flowers, although fewer in number than those carried by the plants which gained Mr. J. Boulton, gardener to R. A. Gibbons, Esq., Northfleet, the second prize, were much finer and well developed, and the foliage too was much superior. The best four standard-trained large-flowering varieties, staged by Mr. Phillips, consisted of George Glenny, Mrs. Dixon, Venus, and Mrs. G. Rundle. A good plant of Mrs. Fossyth gained the same exhibitor the first prize in the class for a single specimen; and he was again first in the corresponding class for a pyramid with Golden Christine. Mr. J. Boulton and Mr. B. Lambin, gardener to J. T. Dismore, Esq., Gravesend, both showed excellent plants in the foregoing classes. In the gardeners' class for twenty-four cut blooms, incurved, Mr. W. Green, gardener to R. Dunbar, Esq., Greenhithe, secured the premier position with a good stand. Some of the best blooms were the Empress of India, Golden Beverley, Prince of Wales, and Golden Queen of England. The The annual Exhibition of this Society, held at the Milton Hall Beverley, Prince of Wales, and Golden Queen of England. The best twelve incurved blooms were staged by Mr. G. Pendred, gardener to S. C. Umfreville, Esq., Greenhithe, particularly noticeable among them being Nil Desperandum, Gloria Mundi, Queen of England, and Beauty. Mr. Pendred was also placed first with twelve cut blooms of Japanese varieties, all being good; and Fulgore, Elaine, and The Sultan especially so.

Fulgore, Elaine, and The Sultan especially so.

For a collection of fruit, not more than twelve dishes, Mr. J.

Kitchingham, gardener to C. Spencer, Esq., Gravesend, was placed
first with a creditable collection, Apples and Pears predominating.

In the class for three bunches of Grapes, any variety, Mr. Green
obtained the premier award with well-grown Black Alicante; the
second prize being awarded to Mr. T. Wright, gardener to E.

Bryant, Esq., Gravesend, for good examples of Mrs. Pince. Several
good collections of vegetables were staged in the unlimited class.

The attendance was good, especially on the first day of the
Show.

Show. BALING AND ACTON.

This Society held their autumn Exhibition of Chrysentheman fruit, and vegetables in the Drill Hall, Ealing, on Thursday and Friday last week. The weather was most winterly, snow falling heavily on both days of the Exhibition. The Show and the display nearly on both days of the Exhibition. The Show and the days of plants and flowers were most praiseworthy; Potatoes, Onions, and other vegetables, particularly the former, being unusually abusdant and excellent. Several collections of fruit, particularly those from Mr. Hudson, gardener to H. J. Atkinson, Haq., Gunnersbury House, Ealing, were in prime condition. Several large groups of miscellaneous plants were exhibited, and added materially to the effective arrangement of the appelious hall. The large platform miscellaneous plants were exhibited, and added materially to the effective arrangement of the spacious hall. The large platform 22 feet by 9 was completely filled by a group of fine-foliage and flowering plants admirably arranged by Mr. Hart, gardener to T. Nye, Rsq., Castle Bar, Rahing. The first prise was deservedly awarded to this very meritorious collection. Rqual second prises were awarded to Mr. R. Fountain, gardener to Miss Wood, Ealing, and Joseph Moore, Esq., Queen's Walk, Castle Bar, Rahing, which consisted chiefly of well-grown Ferns, Chrysanthemums, and inefoliage plants. Mr. Thomas Pestridge staged an admirable group, amongst which were several well-bloomed plants of that lovely and pure white Pompon Chrysanthemum Mdlle. Marthe, a variety most suitable for market purposes. There were also in this ellection several plants of Pteris stramines, a variety very popular for market purposes, but otherwise seldom met with in large quantities. quantities.

CHRYSANTHEMUMS. - In the principal class for est blooms

special prizes were offered of £3 8s., £2 2s., and £1 1s. for twenty-four blooms, eight to be Japanese and sixteen incurved. For this there were three good collections. Mr. Moorman, gardener to Miss Christy, was awarded the first prize for a highly meritorious collection; Mr. Clarke, Rochampton, being placed second, and R. Nye, Rsq., Guildford, third, all exhibiting well. Several local growers competed in the many classes set apart for them, but the majority of the collections were not up to the standard. Messrs. C. Lee & Son exhibited several boxes of Chrysanthemum flowers,

C. Lee & Son exhibited several boxes of Chrysanthemum nowers, very many of them being of great substance.

The Society's first-class certificate was awarded to Messrs. Kelway & Son for a dwarf tufted form of Scolopendrium, almost as finely curled as good Parsley, named S. vulgare Kelwayi, and to Mr. R. Dean for Calendula Meteor, a very pretty Marigold. The arrangements were well carried out by Mr. R. Dean, the Hon. Secretary, assisted by his brother and some very active members of the Committee.

TOROUAY.

This Show was held on the 11th November, and proved in many seepects very satisfactory. The prizes for collections of Chrysanthemums in pots were mostly divided between Mr. R. Hannay and Rev. J. B. Tomlinson. In the class for six Pompon Chrysanthemums, Col. Campbell of Villa Como secured the first prize with fair plants. In the nurserymen's class for twelve distinct varieties in pots Messrs. Curtis, Sandford & Co. were first with well-grown

in pots Messrs. Curtis, Sandford & Co. were nest with wen-grown plants.

The cut flowers were most excellent. The Judges must have had some little difficulty in coming to a decision in several cases. In the open class for eighteen distinct large-flowered Chrysanthemums the first prize went to the Misses Carew, the second to Capt. Tucker. In the amateurs' class for twelve, first prize Mr. W. J. Watts; second Misses Carew. In this class some most excellent blooms were staged. Mr. Watts's were set up the best and were not so crowded, the black velvet-covered stage suiting the Chrysanthemums extremely well. In the other classes too much Chrysanthemums extremely well. In the other classes too much cannot be said in praise of the twelve blooms of Mrs. Dixon and twelve of Mrs. George Rundle exhibited by the Misses Carew and Mr. John Clements. The gardener is to be congratulated upon his success.

The fruit competition was not very close. The Rev. W. H. Gretton was first in most of the amateurs' classes for Pears and Apples, he staged good collections. Judges are not infallible, or those at Torquay would never have decided in Class 59 as they did. The prize was for "six fruit of any other sort." Mr. Gretton and the deligious Powers du Competent. chi. The prize was for "six fruit of any other sort." Mr. Gretton exhibited very well indeed the delicious Doyenné du Comice, but was placed second to Mr. Retty, who elected to show six not very large Belle de Jersey. Some people may prefer a stewing Pear to a luscious dessert fruit.

In order to encourage nurserymen to send fruit to this Show the Committee offered two prizes, £3 and £2 respectively, for best collections of Apples and Pears, all varieties to be correctly named. Messrs. Cranston & Co. had entered for this class, but when their representative found that a Jersey fruiterer had entered he withdrew from the competition. I believe the Judges expressed an drew from the competition. I believe the Judges expressed an opinion that Jersey and foreign growers should not be allowed to compete on the same terms with English growers. Mr. Pluck of St. Heliers, Jersey, received the first prize for a collection consisting of thirty-four varieties of Pears and twenty-eight of Apples. It was certainly an excellent collection. Means. Cranston exhibited their fruit, which considering the past season was worthy of the well-known firm.

There were some good dishes of vegetables shown, including some marvellous Leeks. The attendance at this Show was very large, the room being quite uncomfortably crowded.—J. A. W.

NOTES AND GLEANINGS.

In reference to the recent FALL OF SNOW Mr. B. Inglis writes as follows:—"After six weeks of beautiful autumn weather (during which very little over 1 inch of rain has been registered) the Cuckfield district of Sussex was visited at the end of last week with a very heavy snowstorm. About 4 inches fell on Thursday morning the 20th, much of which thawed during the day. It again commenced snowing at half-past eight on Friday morning, and before eleven o'clock 8 inches had fallen. It continued to snow during the day and intil midday on Saturday, when the average depth would be about 15 inches. Not less than 20 inches had fallen in the Gree days." A correspondent writing from Edgware, Middleskx, states that on the 16th inst. the thermometer registered 20 of frost, and on the 23rd inst. 21°. We also hear from several other localities of equally low temperatures.

— AT a meeting of the Executive Committee of the NATIONAL ROSE SOCIETY, held on Tuesday last, it was annonced that the following special prizes would be competed for it the exhibition to be held at the Crystal Palace on Satuday, July 3rd, 1880:—1, Silver challenge cup (general

competition), given by Messrs. Cranston & Co., Hereford. 2, Silver cup, value ten guineas, given by John Hollingworth, Esq., Maidstone, for the best box in Class 1, seventy-two Esq., Maidstone, for the best box in Class 1, seventy-two varieties, nuryserymen. 3, Silver cup, value six guineas, by Thomas Hollingworth, Esq., Maidstone, for the best eighteen Teas (nurserymen). 4, Silver cup, value ten guineas, by R. N. G. Baker, Esq., Heavitree, Exeter, for the best eighteen Roses (nine Hybrid Perpetuals and nine Teas), amateurs. 5, Silver cup, value ten guineas, for the best stand of Cheshuntraised Roses, by Messrs. Paul & Sons, Cheshunt. 6, Piece of plate, value three guineas, for the best stand in Class 14 (suburban Roses), by Edward Mawley, Esq., Hon. Sec. 7, Five pounds for the best seedling Rose not yet in commerce, by G. P. Hawtrey, Esq., Langley, Slough. 8, Silver-gilt medal, by the proprietors of the "Journal des Roses," for the best twenty-four Roses, three of each, one fully expanded, one half open, and one in bud. open, and one in bud.

- GREVILLEA FILICIFOLIA is a much superior form to that usually grown—viz., G. robusta, which is, by the way, a plant we cannot do without, but when you see the two ferms standing side by side it is no difficult matter to give an opinion of their respective merits. The leaves of G. filicifolia are much more finely cut, and rather more graceful in their disposition. Plants when well grown are very handsome. Most likely it is a selection from G. robusta, therefore we must not expect to have it in such quantities as we do that plant, since seed is not obtainable. It is, however, very easily grafted on robusta stocks, and greater success is realised if the leader of the stock is not cut off entirely. It was, we think, exhibited by the late firm of Rollissons at Tooting, but never received

the attention it richly merits.

In our report of the CHRYSANTHEMUM Show at the Royal Aquarium Messrs. Dixon & Co. were accredited with having received the first prize, a silver cup, in the class for a group of Chrysanthemums; whereas Mr. Hall, gardener to W. Stevens, Esq., Tulse Hill, was the honoured individual, Messrs. Dixon receiving an extra prize. The mistake was due to the unnecessary delay and inefficient system adopted in affixing the prize cards to the several exhibits. Mr. Hall's plants were exceptionally good, well trained, compact, and well flowered. A specimen of Faust was remarkable for the regularity and substance of the flowers, which were well backed up with foliage. Mrs. Dixon, Mrs. Haliburton, Julie Lagravère, and St. Michael were also in fine condition. Mr. J. Balaam, Vine Nursery, and Mr. J. Rickett, gardener to Mrs. Bowerbank, Stoke Newington, followed in the class with much inferior collections. Mr. H. Cannell, Swanley, exhibited an excellent stand of Zonal Pelargonium blooms, which were highly commended.

- THE CAMELLIAS in the Victoria Nurseries, Upper Holloway, give promise of a grand display of flowers, for the buds are uncommonly numerous, and the general health and vigour of the plants all that could be desired.

- In the Orchid house at Kew that lovely little species IONOPSIS UTRICULARIOIDES is now flowering. interesting plant would scarcely be taken for an Orchid by a casual observer, so distinct are the flowers from the normal type, resembling, as the specific name denotes, the Utricularia, and they appear at a glance by no means unlike the common Lobelia in form. The flowers are small, and are borne in a paniculate inflorescence; they have a flattened two-lipped appearance, the lower lip protruding and two-lobed. The colour is white, delicately tinged and streaked with pale rosy lilac. The plant is a native of Trinidad, and was introduced to this country about 1822, but is rarely seen in culti-

AMONG many other plants that Messrs. Cutbush & Son of Highgate and Barnet grow remarkably well are DOUBLE WHITE PRIMULAS, of which there is a fine batch at their Highgate Nurseries. These beautiful plants when well grown are invaluable for decorative purposes at this period of the year. We also observed a semi-double variety with flowers of a delicate blush tint; it appeared to be of good compact habit, and profuse in flowering.

- HAZELS AND FILBERTS have been unusually abundant, the kernels remarkably large and well flavoured, a small farmer himself gathering 2 stones of Hazel nuts and selling them afterwards (Mid-Lincoln). In stone fruit this year, especially Apricots, the kernels were also very large, and much more frequently double than in other years. The Scotch Champion POTATO has been most successfully grown in this neighbourhood. It is very sound, deep-eyed, firm, but deliciously floury in texture, bursting up like a flourball when steamed, but not bearing boiling.

A SPECIMEN of that attractive Myrsinaceous plant JACQUINIA AURANTIACA is bearing numerous clusters of its dark orange-coloured fragrant flowers in the Palm stove at Kew. This species is a native of the Sandwich Isles, whence it was introduced in 1796. The leaves are coriaceous and dark green, the flowers being borne in small clusters on the branches.

—— THE EUPHORBIA.—Some few years since a survey was being carried out in Natal for the Colonial Government, during which it was discovered by one of the officers engaged on the work that when certain plants belonging to the natural order Euphorbiacese were cut with the clearing knives the exudation from the plants adhered firmly to the blades, and was very difficult to remove. It was, moreover, found that the knives so coated did not rust, and this led to further experiments being made with a view of utilising the gum as a preservative material. Iron plates were coated with the gum and subjected to immersion in the waters of South Africa, which are stated to be proverbial for their foulness and for the rapidity of the growth of vegetation. The Euphorbia in Natal grows in close contiguity to the seashore, so that there was ample opportunity for securely testing its value as a protective covering for iron against corresion and marine growth. The experiments proving perfectly successful, it was then sought to put the discovery into a practical form. To this end the gum was dissolved in a preparation of spirits, and this was found to be a ready means of applying it as a coating for ships' bottoms and for ironwork generally requiring such protection, the spirits evaporating and the gum being left on the surface of the metal. With this preparation experiments were made a few years since by Sir Andrew Clarke, C.B., who had a sheet of iron coated with it and placed in the waters in Her Majesty's dockyard at Chatham, where anything immersed becomes rapidly fouled. At the end of two years the sheet of iron was taken out and was found to be quite clean, and free from fouling and corrosion. The composition has also been successfully tested in Africa against the ravages of the white ant. This success is attributed to the circumstance that the gum of the Euphorbia, which forms the base of the fluid, is of such an intensely bitter nature that it paralyses the efforts of all insects to attach themselves to it, or to bore into any substance coated with it. These successes have led to its adoption in practice for the purposes above indicated, and it is now being introduced in England. Applications of this composition give a glossy coating alike impervious to air or moisture, while, according to results, its own peculiar protective property remains unimpaired,

THE METEOROLOGICAL SOCIETY.

THE METEUROLOGICAL SOCIETY.

The first meeting of this Society for the present session was held on Wednesday, the 19th instant, at the Institution of Civil Engineers, Mr. C. Greaves, F.G.S., President, in the chair. The following gentlemen were elected Fellows:—Capt. C. K. Brooke, Rev. E. Carr, M.A., Capt. R. A. Edwin, R.N., W. B. Fawcett, C. J. Harland, J. Lucas, F.G.S., H. Mellish, G. B. Nichols, The Earl of Northeak, Dr. J. Robb, T. H. Walker, and C. L. Wragge, F.R.G.S. The reports on the Phenological Observations for 1879 were read—the botanical being by the Rev. T. A. Preston, M.A., F.M.S., the entomological by the Hev. C. H. Griffith, B.D., F.M.S., and the ornithological by J. Cordeaux. With the exception of a few days in the earlier parts of February and of March the whole of the year 1879 has been characterised by a temperature almost invariably below the mean, accompanied with much wet and little or no sun; the effect on vegetation has been consequently very great. Foliage has as a rule been excessively luxuriant and dark, forming the most remarkable feature of the year; but rarely has fruit been able to ripen, and the second shoots have frequently been weak and unhealthy. Flowering has invariably been very late, so much as a month in some districts, the hay harvest often not completed till nearly the end of August, some still in "cock" in the moorland district of Staffordshire as late as Esptember 80th; and the corn harvest, not only extremely late, but the corn in very poor condition, not properly ripened. With regard to insects, the two most notable occurrences of this most dismal season have been the swarms of Pyrameis Cardui and Plusia gamma; both these species have been wonderfully numerous, especially the latter, which has absolutely swarmed. The great severity of the past winter caused an almost unprecedented mortality amongst birds, great numbers of various species succumbing to the cold. This mortality was perhaps most apparent amongst the Turdides and the starlings. Spring brought little or

instances the first eggs have been addled and destroyed by cold rains and an abnormally low and continuous temperature. The scarcity of young partridges is probably unprecedented; on some manors not a young bird is to be found, and it will take several good nesting seasons to bring up the stock of their old numbers.

manors not a young bird is to be found, and it will take several good nesting seasons to bring up the stock of their old numbers. A paper on the Meteorology of Zanzibar, by Dr. John Robb, was also read. The average annual rainfall is rather more than 61 inches, or only about double the average yearly fall in England, and the average number of rainy days is 120. The greater rains fall in March, April, and May; the lesser rains are from mid-October to the end of the year. The driest month is September, with an average rainfall of 1.86 inches; no month is rainless. The mean temperature of five years is 80.6°, and the average yearly range, from highest maximum to lowest minimum, is 17.8°. The hottest months of the year are February and March, with a mean temperature of 88.1° and 88.4° respectively; the cool months are July and August, averaging 77.5° and 77.7°. This gives a small amplitude of the yearly fluctuation, rather less than 6°, and to this limited range of temperature is largely due the debilitating nature of the climate of Zanzibar, particularly as affecting the nervous system. The heat is constant and moist, and even gentle exercise is usually attended with excessive perspiration.

THE ROSE.

A CORRESPONDENT ("SOUTH DEVON") asks, "Can you inform me which is the oldest known variety of 'the queen of flowers?'" In reply we will quote from Parkinson's "Paradisus Terrestris," published in 1629, who declares that he names the varieties chronologically. He places first the English White Rose, and then follow Carnation Rose, English Red Rose, Damask Rose, Double Province Rose, Red Province Rose, White Province, York-and-Lancaster, Crystall, Gilloflower, Frankford, Hungarian, Velvet, Thornless, Cinnamos, Yellow (single and double), Musk, Apple, Sweet Briar, and Evergreen.

Mr. Rivers says of the Provins or Cabbage Rose (Rosa centifolia), "This Rose has long and deservedly been the favourite ornament of English gardens; and if, as seems very probable, it was the Hundred-leaved Rose of Pliny and the favourite flower of the Romans, contributing in no small degree to the luxurious enjoyments of that great people, it claims attention as much for its high antiquity as for its introduction to our gardens. That 'prince of gardeners, Miller, says that it is the prettiest of all Roses; and this ides still prevails to a great extent in the agricultural districts of England, where, in the farm and cottage gardens, the Cabbage Rose and the double Wallflower are the most esteemed in mates, forming in their turns, with a sprig of Rosemary, the Sunday bouquet of the respectable farm servant and cottager.

"The groves of Mount Caucasus are said to be its native places of growth, and also Languedoc and Provence; but the claims of these latter have been disputed. I lately wrote to a very old Rose amateur in France for information on this point. He informs me that the species with single flowers is found in a wild state in the southern provinces; it is therefore very probable that it was called the Provence Rose from growing more abundantly in that province. The more correct name is the Provins Rose, from its being so long cultivated about Provins in the old province of Brie-Comte-Robert, where the great culture of Roses in France in still conducted. It has now, however, quite a different name in France, for it is called the 'Rose's Cent Feuilles,' from the botanical name, Rosa centifolia, or Hundred-leaved Rose.

"The Crested Provins, Crested Moss, or Rosa cristats, for it it known by these three names, is said to have been discovered growing from the crevice of a wall at Friburg in Switzerland. No Rose can be more singular and beautiful: the buds before expansion are so clasped by its fringed sepals that they present a most unique and elegant appearance totally unlike any other Rose,"

LUCULIA GRATISSIMA.

This beautiful ally of the Cinchonas is well known in most establishments where large collections of plants are grova, and it is worthily esteemed for the globular cymes of pak fragrant flowers that are produced so freely under suitable culture. The time of year at which the Luculia flowers—it, autumn and winter, is also a recommendation of consideable importance, for not only is the plant highly decorative either grown in pots or planted out in prepared borders in a freenhouse, but its value is inestimable for cutting purposes, a the

flowers are so continuously and abundantly produced. Such qualities as those mentioned justly entitle the Luculus to more general notice and cultivation, and as its requirements are few say person who possesses a greenhouse or conservatory may askedy venture to obtain a specimen. When planted out it rapidly acquires the proportions of a shrub or small tree, and

requires to be well pruned after flowering is over; but per-hape it is of more general value when grown in pots of medium size, say 32's, and plants in that size pots or a trifle larger may by good treatment be had bearing clusters of flowers fully as large as that represented in the engraving.

With regard to its cultivation we may remark that it is

especially averse to a superabundance of water or the least apespecially averse to a superabundance of water or the least approach to stagnation at the roots or in the atmosphere. Therefore a perous soil must be provided composed of loam, peat, leaf soil, sand, and a few pieces of charcoal thoroughly incorporated, and whether the plant be in a pot or a border, the drainage must be well attended to. When growing freely, or about to flower, weak liquid manure may be occasionally supplied with advantage. Propagation is easily effected by taking cuttings of the young firm wood, with a heel of the old wood attached, and

insert them in similar soil to that already described, employing rather more sand. They should be placed near the sides of the pots, the latter being plunged in good bottom heat and covered with a beliglass. When the cuttings are rooted shake them out carefully, and pot them singly in thumbs or 60's, afterwards increasing the root room as the plants advance in growth, but being careful not to overpot them. When thoroughly established they may be grown in any cool or intermediate house where the temperature is not allowed to fall much below 50° at

night at any period of the year. If planted out they succeed well under similar treatment to the Camellia (with which they are sometimes associated) in respect to temperature and moisture.-- L. CASTLE.

NOTES ON VILLA AND SUBURBAN GARDENING.

In the kitchen garden department the work will principally consist in protecting the crops for the winter's supply, and in consist in protecting the crops for the winters supply, and in digging, trenching, and preparing ground for the spring. Compost and manure heaps should be formed and turned over, and manure wheeled on to the ground during very dry or frosty weather. Where early Peas are required, and a warm position in weather. Where early reas are required, and a warm position in the garden can be allotted to them, a few rows of seed may be sown. If the winter is mild they will be about a fortnight in advance of those sown in the spring. Dickson's First and Best or Carter's First Crop 'are among the hardiest for this purpose. Celery will now require its final earthing on dry mild days, but in many gardens around London this delicious and favourite vegetable is in very bad condition. In our garden, and in others regetable is in very bad condition. In our garden, and in others where we have seen it cultivated in a state of excellence in other years, a good stick of Celery cannot be found, the foliage is completely destroyed by the Celery fig. In spite of repeated dustings with soot and lime this insect has survived, probably owing to excessive wet, so that directly the plants were dusted heavy rains washed it from the surface of the leaves. In other quarters we hear complaints of the plants running to seed. To make the best of that which we have we must earth-up the plants well, and during frosty weather protect the rows with bracken or litter. Caulifiower and Lettuce plants in frames or under handlights

Cauliflower and Lettuce plants in frames or under handlights Cauliflower and Lettuce plants in frames or under handlights should have air admitted to them on every fine day, but during severe frost a protection of bracken or other covering is very essential. Globe Artichokes should have the leaves of each stool gathered up close together when dry, and a band of hay or straw twisted round them and a few dry leaves placed outside to protect them through the winter. So severely damaged were they during the winter of 1878-9, that no early crowns were to be obtained. During September and October many of them produced heads which have continued till the late frost. Jerusalem Artichokes are best preserved in the ground but require protection from frost are best preserved in the ground, but require protection from frost. Cut off the stems about a foot from the ground and spread over then a thick layer of dried fern, litter, or leaves, and dig for use as required. Rhubarb and Seakale—If a few roots of each of these are placed under the stages in boxes in a stove or other warm structure they will furnish a supply of produce before it is necessary to start the main crop out of doors. A thin layer of litter or leaves placed over the crowns in the beds will not only protect the roots, but allow them to be taken up at any time, even during frosty weather. Carrots and Beet if not already lifted must be attended to at once, and the roots laid in sand to keep them plump and fresh. The tops of Beet should be twisted off by the hand. Beet is in most places unusually small this year from the heat having been insufficient to mature it.

CONSERVATORY.—This structure is now bright with Chrysanthemums. How beautifully chaste in appearance are many of the Japanese varieties, while the more formal symmetry of the incurved forms contrast admirably with them. The Anemone the Japanese varieties, while the more formal symmetry of the incurved forms contrast admirably with them. The Anemone varieties are also very beautiful in their way, while the beauty and habit of the Pompon and Anemone Pompons render them very valuable for forming the front rows of groups. Thus when flowers are destroyed outside, a most brilliant display can be had within with Chrysanthemums alone. Their cheapness and simplicity of culture place them within the reach of all. That the past season has not been the most favourable for bringing them to perfection must be admitted, yet there are some excellent flowers to be seen, and many a conservatory is now gay with them that otherwise would be gloomy. Pay great attention in giving air on all favourable occasions; keeping the air around them dry is the best way to preserve them. Araleas, Bhododendrons, Deutzias, Spiræas, Lilacs, &c., are among the best hardy plants suitable for forcing and for producing a display in the conservatory when the Chrysanthemums are past; Roman Hyacinths and other bulbs should be brought gradually forward; and amongst the greenhouse plants coming into flower are Heaths, Epacrises, Cytisuses, Coronillas, Acacias, Eupatoriums, &c., Primulas, Cyclamens, and Cinerarias following.

WORK FOR THE WEEK.

KITCHEN GARDEN.

TURN up all vacant ground roughly, and in the case of heavy TURN up all vacant ground roughly, and in the case of neavy soil ridging up so as tolexpose as large a surface as possible. The advantages of deep cultivation cannot be over-estimated—it is the first principle in high culture. Trenching should be practised every second or third year, seeking by loosening the lower strata to increase the depth of shallow soils, and by bringing up a little fresh soil at each trenching the soil may be permanently improved. Manure buried in autumn or early winter is not nearly so beneficial as that which is spread on the surface during frosty weather and

pointed in at a later period. Thoroughly decomposed manure is very much better for affording satisfactory results in gardens than very much better for affording satisfactory results in gardens than crude material buried in autumn. The rubbish heap should have attention betimes. All material that is decayed sufficiently for immediate dressing should be separated from that which will require more time for decomposing, and if a ton of lime be added to every six of refuse the decay will be more speedy and effectual.

FRUIT HOUSES.

Cherry House.—The leaves having fallen the trees should be attended to in pruning, but if stopping has been attended to during the period of growth it will only be necessary to cut back any shoots not required for filling vacant space. Young trees in course of formation will require to have the central shoots nn course or formation will require to have the central shoots cut back as may be necessary to provide a supply of regular growth for the allotted space. Except for the purposes indicated it is not advisable to shorten the terminal shoots, unless it be necessary from the limit of the trellis being reached, or if the trees are confined to pots. The house should be thoroughly cleansed, and the trees also. If the lights have not been replaced it should be done and the house fully wentileted avent in cleaned, and the trees also. If the lights have not been replaced it should be done, and the house fully ventilated, except in very severe weather. Plum trees in pots which are to be advanced by forcing should also be pruned, shortening back all last year's growth, superfluous shoots being cut out entirely, avoiding having the shoots too thickly placed, uniformity in appearance being considered, and the knife used accordingly.

Strawberries in Pots.—A commencement should be made in forcing by placing plants of an early variety in gentle heat to

Strauberries in Pois.—A commencement should be made in forcing by placing plants of an early variety in gentle heat to afford ripe fruit in February. Black Prince is still the best very early variety, and if well thinned the fruits are of fair size. Vicomtesse Hericart de Thury, though not subject to mildew or the production of deformed fruit as Black Prince, is not nearly so Vicomtesse Hericart de Thury, though not subject to mildew or the production of deformed fruit as Black Prince, is not nearly so large as La Grosse Sucrée, whilst Sir Harry affords fruits both of good size and colour. The drainage in the pots must be rectified if it be found defective. The surface of the soil should be lightly stirred, top-dressing with horse droppings, which will prevent the surface from cracking, and if a little bone dust be given to each plant it will be an advantage. The pots should be placed on shelves near the glass where the plants can have plenty of air, and from first to last they must not suffer by want of water. The house, if one be available, will only require to be kept closed the first fortnight, providing the night temperature does not fall below 45° and the temperature by day be 50°, above which air should be freely admitted. Failing a Strawberry house an early Peach house or vinery will be suitable, the plants being assigned positions near to the glass. It is important that the plants be not too much hurried in the early stages, or the foliage will be drawn and thin and the flowers weak; besides, the season has been sounfavourable to the plants maturing the growth that more than ordinary careful treatment will be necessary to effect a vigorous early growth. Autumn and winter-fruiting plants will need to be carefully watered, keeping those well advanced for ripening moderately dry, and admit air freely whenever an opportunity offen, the temperature by artificial means being 60° to 65°.

Pines.—During the next two months the sun will have little effect upon vegetation subjected to artificial treatment. Pines now

Pines.—During the next two months the sun will have little effect upon vegetation subjected to artificial treatment. Pines now effect upon vegetation subjected to artificial treatment. Fines now will be better in a diminished temperature than that hitherto accorded them, particularly young growing plants. A temperature of 55° is a safe minimum, ventilating at the upper part of the house at 58°, allowing the temperature to rise to 60° or 65°, with a house at 58°, allowing the temperature to rise to 60° or 66°, with a liberal supply of air, and the temperature at the roots should be 70° to 75°. In the fruiting department the temperature from fire heat may be lowered to 65°, or in severe weather 60° at night and 70° to 75° by day, and successions under ordinary treatment 60° at night, falling to 55° on cold mornings, and 65° by day. At the commencement of next month the temperature at the roots of Queen plants, which are required to start into fruit early in the ensuing year should be gradually raised to about 90°.

Cucumbers.—For the next three months be very careful in the admission of air: and while a little should be given at every

Cucumbers.—For the next three months be very careful in the admission of air; and while a little should be given at every favourable opportunity, it should certainly be excluded as far as in possible when it is cold, chilling draughts being very injurious to the plants. Keep a moderate amount of moisture in the atmosphere in bright sharp weather. Attend to stopping, thinning, and tying the shoots, cropping lightly, removing without delay any decayed portion of stem or leaf, and keep the glass clean. Maintain a night temperature of 65°, falling to 60° on frosty mornings, and 70° to 75° by day from fire heat.

Figs.—When the foliage has fallen the trees should be pruned. Shoots which have attained the limit of the trellis should be cut

Shoots which have attained the limit of the trellis should be cut back to where the succeeding shoots start, in order that they may occupy their places in the ensuing season. Cut away entirely all elongated spurs, reserving, however, as may be desirable, a few of those which are short-jointed and fruitful. The trees should after pruning be loosened from the trellis, and after thoroughly cleaning the woodwork with soars and water the clear with clear with pruning be loosened from the trellis, and after thoroughly cleaning
the woodwork with soap and water, the glass with clear water,
and the walls limewashed, adding a little sulphur, the trees hould
be washed with soapy water with a brush, and afterwards with
some insecticide, avoiding pigments that leave a thick deposit upos
the shoots, and when this is completed tie the trees to the trells,
not too tightly. If the trees have not been lifted the border should

be lightly pricked over, the loose material removed, and a top-dressing, about 8 inches thick, given of short partially decayed manure. The house can hardly be too freely ventilated, only when frost prevails it must be closed. The earliest batch of trees in pots should again be dressed with an insecticide, care being taken not to rub off the young fruits. The trees may be put in a mild bottom heat, the pots being placed on pillars of loose brickwork, so that they will not settle with the fermenting material. The heat at the roots must not exceed 60° to 65° until the trees are fairly in growth, whilst the top heat may be 50° to 55° at night and 65° by day, the trees and house being damped in the morning of fine days early in the afternoon. A commencement should mg of the days early in the arternoon. A commencement should be made from now to the end of the month to insure ripe fruit at the end of April and early in May. Water must be given at the roots to keep the soil thoroughly moist, and not less in temperature than that of the fermenting materials about the pots.

PLANT HOUSES. Grandous.—Liliums should be examined, and if not yet potted no time should be lost in completing the work before they begin to push fresh roots. Some of the earliest-flowered L. auratum and L. longiflorum will by this time be fast producing their new fibres and should not be disturbed. If the pots are large enough simply remove the surface soil and that around the bulbs, dressing with fresh well-enriched compost, or if the pots are too small simply transfer the bulbs to larger pots without disturbing the ball. The drainage must in the first case be examined, and if defective rectified, and in the latter be provided efficiently. The great bane of L auratum and L longiflorum is dryness at the roots, they being more impatient of this than most varieties. It must not, however, be supposed that water must be given unstintedly, as the soil in that case would become sodden and the roots would perish. The potting of all Liliums should always be carried out as soon as the stems have died down, as although some portions of the roots of many varieties are never quite dormant, still at the time when the tops have lost their vitality there is the least root-action. In the case of large masses of bulbs that have increased until it is necessary to divide them, it is still more important that it be done withand leaf soil in equal proportions, and sand in proportion to the character of the loam, suits Lilies. The bulbs should be placed as deep in the pots as to admit of about 3 inches of top-dressing, so that none of the roots that are formed above the bulb will appear above the surface of the soil. Neglect of this often results in serious injury to the plants. They should not be placed beneath traces injury to the plants. Increase a stages where they are exposed to the drip from other plants. Tropesolum tricolorum, T. Jarratti, &c., will now be advancing in growth, and should be kept near the glass and regularly trained. it with the bark on forms a suitable support, training the thread-like ahoots evenly over it, attending to them regularly, or the shoots become so entangled as to prevent the possibility of making the plant at all presentable afterwards. The bottom of the trellis must in all cases be well covered with the young growth before the shoots are allowed to ramble at the top, or there will afterwards be a difficulty in furnishing the base. Avoid overwatering, but keep the soil moist. Echeveria retusa encouraged with a gentle heat will soon be in flower and last for several weeks; it and Repatorisms require to be near the glass, the latter not being allowed to suffer from insufficient water; and by placing a few plants in a little extra heat they will precede those kept in an ordinary greenhouse, thereby securing flowers over a longer period.

Epacrises may be placed in a little extra heat, which will quickly bring them into flower, when they will be found very useful for ervatory decoration or for cuttings of the long shoots. Specimen hardwooded plants should be cleaned and tied. All dead foliage should be removed and the surface of the pots cleared from moss. should be removed and the surface of the pots cleared from moss. In replacing the sticks take all the old stumps out of the soil, as they do much harm to the roots. Avoid tight tying, and employ no more sticks than are absolutely necessary.

Orchids.—The houses should be kept comparatively dry during

could foggy weather, and the ventilators closed. If any plants require watering let it be done in the forencon. The present is a good time to examine the whole collection and give the plants a thorough cleaning. Odontoglossums requiring larger pots may be shifted, taking care not to disturb the roots more than is necessary in removing the crocks from the bottom. These plants succeed best in equal parts of fibrous peat and sphagnum, with a good sprinkling of sand, and as they require a very liberal supply of water thorough drainage is indispensable. Pleiones that have converted and require larger pots should have all the old material removed from their roots; they will thrive in almost any light compost—equal parts turfy loam and peat, also leaf soil and old cow dung, or peat and sphagnum. The pots or pans in which they are grown should be well drained placing some moss or the creek of ling on the within helf an inch of ney are grown should be well drained placing some moss or rough peat over the crocks, filling up to within half an inch of the rim, placing the bulbs an inch apart, and covering over the old roots with half an inch of the compost; water lightly until the roots start into growth. The temperature of the East Indian house should be 60° to 70°, Cattleys and Mexican houses 55° to 55°, sool house 45° to 55°; in bright weather 5° more may be

allowed, and where the nights are unusually cold the temperature

allowed, and where the nights are unusually cold the temperature may be 5° less than the minimums.

Forcing House.—In order to have a good display of flowers during the winter and early spring, forcing must be resorted to and a batch of plants be started. It is desirable that a house or two be set apart for the purpose—light well-ventilated structure, and if possible having a bed for fermenting materials in the house, which will lessen the necessity for fire heat, and be useful for which will lessen the necessity for fire heat, and be useful for plunging the pots in, particularly herbaceous plants. To grow Lily of the Valley satisfactorily early in the season, whether clumps or single crowns be employed, they should be plunged in a bottom heat of 90°, and when sufficiently advanced the inverted pot, which is desirable to cover them with, should be withdrawn and the foliage and flower exposed to light. When an elegant drooping flower is required for the decoration of large vases few blooms are five then the add Schemeir Schl. (Convalue) and the Polymen. plants are finer than the old Solomon's Seal (Convallaria Polygonatum). As a companion plant Dielytra spectabilis is unrivalled, good specimens being very fine for conservatory decoration. Hoteia (Spirssa) japonica is another very elegant and graceful plant, alike useful for cutting or decorative purposes. Pinks such plants, Mire useful for cutting or decorative purposes. I mas seems as Lady Blanche, Mrs. Moore, Anne Boleyn, Lord Lyons, Rubens, and Mrs. Pettifer are from their sweet flowers very acceptable, but they must not have too much heat; a temperature of night and 55° by day, advancing to 60° or 65°, is more suitable for them. Azalea mollis and its varieties force readily, also the English and Ghent in varieties, A. pontica being especially valuable for its fragrance. Rhododendrons, selecting early flowering varieties such as Early Gem. Blanche Superbe, cancasicum album, varieties such as Early Gem. Molleianum. Rought tonianum. ventous such as Emily order, Disaltine Superior, Salcissium album, coriaceam, Nobleanum, Marian, Wellsianum, Broughtonianum, Brilliant, &c., with odoratum for its scent. Kalmia latifolia, Viburnum Opulus, and the indispensable Deutzia gracilis, Spireaz Thunbergi, and Prunus sinensis alba flore-pleno. Staphylea col-Thunbergi, and Prunus sinensis alba flore-pleno. Staphylea colchica will, we anticipate, be extensively grown when it becomes better known. Lilacs are indispensable. To soften the buds the plant should be sprinkled overhead in the morning and early in the afternoon, but where fermenting materials are employed the the afternoon, but where fermenting materials are employed the necessity for sprinkling will not be so great as in a temperature solely derived from fire heat. Christmas Roses, though hardy, flower more certainly in a greenhouse temperature, the best form being Helleborus niger maximus. Where Hyacinths, Tulips, Narcissus are required early a few of these first potted should be placed in heat, 50° to 55° being ample, placing them as near the glass as possibls. If only recently removed from the bed of ashes they should be covered wish inverted flower pots, tilting after a few days, and when the leaves are quite green they may be altothey adould be covered with inverted nower pots, thing siter is few days, and when the leaves are quite green they may be altogether removed. Single sweet-scented Jonquils are easily brought into flower by similar means; and a few pots of Scillas, especially S. sibirica, are useful, as they do not require much heat to bring them into flower. Violets in pots placed in a temperature of 45° to 50° will flower finely if well-formed crowns are employed, and are always acceptable from their fragrance. Those in frames are always acceptable from their fragrance. Those in frames should have all decayed or yellow leaves removed, the soil lightly stirred between the plants, affording air whenever the external temperature is above freezing point. During frost they may remain closed, and must be protected in severe weather. All plants intended for foscing should at once be placed under cover; a pit where sufficient heat can be obtained to exclude frost is the most suitable place for them from whence they can be removed. a pit where sufficient heat can be obtained to exclude frost is the most suitable place for them, from whence they can be removed as required to the forcing house. Roses in pots must also be placed under cover, and if they cannot be accommodated in a house from which frost is excluded, the pots should be plunged over the rims and the stems protected in severe weather.

TO CORRESPONDENTS.

- * All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expenses. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at
- once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

NORTHAMPTON SHOW (Northampton).—If there is no doubt that the Potatoes which were exhibited were diseased the dish ought to have been

disqualified altogether, for it is an invariable rule of all exhibiting that damaged or diseased objects cannot compete against those that are perfect,

DUCHESSE D'ANGLETERRE PEAR (W. Morris).—We never heard of this Pear, it must be a misprint for Duchesse d'Angoulème.

SUPTED RUBBLE FOR LAND (J. E.).—We have had no experience on the subject of your inquiry. Rocks vary much in induration, and some of them do not readily yield to the action of frost and rain, and so become disintegrated. By examining the rubble for yourself that has been long exposed you may best ascertain how far it will be suitable for applying to the land. If it pulverises with tolerable freedom it might be in some degree beneficial, but we doubt if it will have any great effect in increasing its fartility.

TRANSPLANTING SHRUBS (J. M.).—All the shrubs you name will move safely at the present time if the work is carefully done. The positions should be prepared for them before the shrubs are dug up, and as much soil should be retained about the roots as possible. Any rather large bruised or broken roots should be cut off with a sharp knife.

INSECTS ON APPLE TREES (L. R. M.).—The twigs are infested with the black aphis, which may be destroyed with a solution of Gishurst compound, a strength of 3 css. to a gallon of water, applied with a syringe. A fluid conce of parafin well mixed in a gallon of water, and similarly applied, equirting a syringeful of the parafin water alternately in the vessel and on the trees, will also destroy the insects and not injure the wood of the trees. The swelling of the spurs of the Pear tree you have sent are quite natural, but the wood does not appear to be quite healthy. Does your garden require draining? The rusting and cracking of the fruit is attributable to inclement weather when the fruit was in a small state. Very wet clayey soils and poor dry sandy soils also contribute to the cracking of fruit, which does not receive the support necessary for healthy progressive growth.

BARLY APPLE (A Lady).—The Apple to which you refer as ripening on a wall at the end of July was no doubt the Early White Joanetting. Your description of it is very good. Be careful in trying to get another tree to ask for the White Joanetting, as there is also a Red one.

TOMATOES (Notice).—Cut out all exhausted shoots, and do not water the plants too frequently, but give a thorough supply when necessary. Weak liquid manure will be benedicial. Pots 12 inches in diameter are convenient and well adapted to your requirements.

RIPERING THE WOOD OF PEACHES AND NECTARINES (W. T. P. H.),—
If the wood is now unripe very little can be done this season, but you may
increase the heat and admit all the air practicable day and night until the
feaves show indications of falling, when the heat should be turned off. If
the leaves have already commenced failing the trees must not be subjected
to fire heat, but have free ventilation in favourable weather so as to induce
as complete a rest as possible.

as complete a rest as possible.

ROBES IN POTS (Amaleur).—The most suitable compost for Roses in pots is turfy loam rather stiff, with a fourth of well-decayed manure and a sprinkling of bone dust equal to a twentieth of the loam. The temperature of the house should not exceed 48° to 50° by artificial means until they are fairly in growth, when it may be raised gradually to 55° at night and 60° to 65° by day, with free ventilation. If you do not wish to force them early they succeed admirably from January conwards in a greenhouse, assigning them light airy positions. After they commence growth liquid manure should be given at every alternate watering, and when in full growth it may be given whenever water is necessary, taking care not to apply it too strong. Until required for placing in beat the plants should be kept in a cold pit or house with the pots plunged over the rims, and in severe weather afford a grotection of mats in addition to the lights.

Vines is Markow Bordensk (J. A. S.).—You may grow Granes of good

protection of mats in addition to the lights.

VINES IN NARROW BORDERS (G. A. S.).—You may grow Grapes of good quality though you are only able to make a border 2 feet in width. You will need to put in 6 inches of rubble for drainage, and over it a layer of turves grass side downwards. The loam being of a tenscious nature add to it one-sixth of old mortar rubbish and a twelfth part of half-inch bones, incorporating thoroughly. The compost should be applied in a rather dry state and made firm. As to the cubic feet of soil to allow to each Vine, that depends on the space the Vines are to occupy. Vines in pots with 8 feet of rod succeed in pots containing less than 8 feet (cubic) of soil; but we should make the border as large as practicable, allowing at least 13 feet to each Vine, and as much more as you can. It will be necessary to water them liberally with liquid manure when growing. They should be planted when they have commenced growing or when the shoots are about an inch long. Black Hamburgh is most suitable, and a good white companion is Foster's Reedling.

CHRYSANTHEMUMS AFTER FLOWERING (Rector).—They may be wintered. in a cold pit or frame, cutting them down as soon as the flowers have faded. The young shoots should be taken off with a small portion of root stem, and may be inserted singly in small pots, or three around the sides of a 3-inch pot; and the pots being placed on ashes in a cold frame the cuttings will root slowly but surely, keeping them moist, affording slight shade when the sun is bright, and keep them rather close until rooted. They should be transferred to larger pots when the cutting pots are filled with roots, taking out the point of each shoot when about 4 to 6 inches in length. The old plants, if you wish to keep them another year, may be turned out of the pots, removing all the old soil, outting the roots back, and repot in \$ or \$-inch pots.

WINTERING PETUNIAS (A. B. C.).—We do not recognise the plant you were told was a Carnation. The Petunias should be kept near to the glass in a house from which frost is excluded, not giving more water than is sufficient to prevent the foliage from flagging. We should cut the plants back, each shoot to within a few inches of its base, and when the plants have made fresh growth an inch or two in length shift them into pots a couple of inches larger in diameter, and by tying out the plants and supplying with liquid manure after the pots are filled with roots the plants will grow rapidly, and if kept near to the glass and the house well ventilated they will flower freely. The shoots removed may be put in as cuttings, and if kept moist they root safely in a greenhouse, flowering more freely than plants from exect.

CHRYSANTHEMUMS FOR PLANTING AGAINST SOUTH WALL (A Lady Gardener).—There are not many that would not succeed in such a position as from the warmth afforded by the wall they make growth early, and with a slight protection, as that of canvas, the blooms could be protected against autumn frosts. The chief object will be to see that they do not unfier from drought in summer, mulching over the roots with short manure and water.

ing liberally in dry weather. Large-flowered varieties:—Alfred Salter, Mr.
G. Rundle, Mr. Heale, Mr. Forsyth, Miss Hope, Aurea Multiflora, Empress of India, Prince Alfred, Prince of Wales, Progne, Golden Beverley, and Princess of Teck. Japanese: Fair Maid of Guernsey, Elaine, Sollel Levant, La Frisure, Fulton, and La Nymphe. Pompon: Calliope, Cedo Null, Golden Cedo Null, Mrs. Hutt, and Aurore Boreale.

Golden Osdo Null, Mrs. Hutt, and Aurore Boreale.

Herbackburs Plants for Flowering M. Autumn (Iden).—In addition to Phloxes and Michaelmas Daisies (Asters), Anemone japonica, A. japonica alba, Colchicum autumnale flore-pleno, C. autumnale album and var. plenum, Crocus sativas, C. nudiflorus, C. Sieberi, C. speciosea, Cyclame hedersefolium and var. album, Polygonum vaccinifolium, Schisostylis cocines, Sedum spectabile (Fabarium), Statice latifolia, Tritoma Uvaria glaucescens, S. grandiflora. Violets: Victoria Regina and De Parme.

RETARDING PRIMULAS (Idem).—They may be had in flower at the time you wish by removing the trusses of bloom as they appear until the early part of February. Those now shifted into s-inch pots and grown on through the winter will flower at the time wished, removing the trusses if any appear before the early part of February.

NAMES OF PLARTS (J. B. Boyd).—Stapelia bufonia, a native of the Cape of Good Hope, introduced to this country in the beginning of the present century. We should be glad to receive a note on the shrub to which you allude. (C. W. D.).—Buonymus europeus, the Spindle Tree. (J. W. T. Darissgion).—Chrysanthemum frutescens, a useful plant for conservatory decoration during autumn and early winter. (A. Boyle).—It appears to be the leaf of a Hedychium. (H. F. C.).—We cannot give the name of a plant from such a brief description. There are dozens which resemble the one you mention. The tree referred to is Paulownia imperialis. (J. T.)—Specimens insufficient for identification.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE APPLICATION OF CHALK AND LIME TO LAND.

(Continued from page 414.)

In almost all cases where the lower chalk can be obtained it should decidedly have the preference over the hard white upper chalk with flints in it, because we have seen it lying on the ground for years in large lumps, on which the frosts have had but little effect in reducing. This has been the case more frequently when the chalk has been applied during the spring and summer months, for the sun and wind will harden it so that it may be used in building walls, sheds, &c. It is desirable that chalk should be laid out in the winter months, and it is also best to get it in a fine state for laying out, otherwise the lumps should be broken by stone-breaking hammers as fast as spread, into pieces not larger than a hen's egg. In those localities where only the hard white chalk can be obtained it would curtainly answer the purpose better to burn it into lime instead of using it as chalk, as by that means it would not only become more quickly and intimately mixed with the soil, but the carriage of the article would be greatly reduced—in fact, to nearly onehalf. As we have before observed that 100 tons of good chalk when burnt should yield 56 tons of lime, but when it leaves more than that it shows that the chalk has been imperfectly burnt by still retaining a portion of its carbonic acid, or that it is of an inferior description, containing many impurities. Then it is important for the home farmer to consider which is chespest—to carry 100 tons of pure chalk for long distances, and after being laid out remaining on the ground for a long time in large humps, from which the crops can derive but little benefit; or go to the expense of having it burnt into lime, thereby reducing the carriage to 56 tons, and it is in such a state that the first shower of min disseminates it all over the ground. In many districts we have seen lime kilns attached to estates some distance from the chalk, others near and attached to the chalk pits, so that the process of burning may be going on continually, and thereby affording parties who live at a distance the opportunity to use lime instead of chalk. In various parts of England and Scotland-where the only carbonate of lime is a hard rock, composed of fragments of corals, &c.—it must of necessity be burnt, otherwise it would be of no value for agricultural purposes.

It is found that the application of 20 tons of chalk per acre will last about twenty years on dry friable land under a system of close cropping, but under ordinary farming, say the four or five-course rotation, we have on our property found that it will benefit vegetation for a period of twenty-five years, and on

strong soils, when 80 or 40 tons are applied, for thirty years. We have chalked our land twice, and in letting land we always, when possible, arrange with the tenant to chalk a given number of acres every year, being paid by the next tenant a proportion of the cost extending over a period of six years. Tenants often object to apply chalk, saying they cannot afford it; but they can afford and do manure the land with purchased manures. We should therefore consider chalk as manure—in fact, it is more than manure, for manure will not be effective where chalk or lime is absent from the soil. Even if one course of manuring was omitted, and chalk applied instead, it would be in favour of chalk at the end of a term of occupation or the end of a tenancy.

The mode of obtaining chalk is various. Sometimes it is only obtained by drawing it a distance of seven or more miles : sometimes on farms near the coast it is obtained by water carriage. Kither way it is very expensive. In case, however, when we have strong loams upon the clay resting on chalk it is the best practice to dig wells for it in the field where it will be required for use, and this is often the best of chalk, being of the lower strata, of a brownish colour, and generally without flints. The chalk when brought to the surface is wheeled out with barrows, the work of digging, bringing to the surface, and spreading being done at so much per acre, and it is certainly the cheapest plan we know, and when done in this way the quantity applied is seldom less than 40 tons per acre, and it is certainly none too much upon the heavy land we are referring to. We often find that the soil on the hill farms which appears near the surface, and is called white land, is ploughed deeper to bring up chalk. This practice on the hard or upper chalk fails, because it is rubble instead of chalk -that is, it has been robbed of its virtues by the roots of plants and the action of air and water for generations, and instead of chalk it has become rubble and more like gravel than chalk, and when brought into work makes the land too loose and light, and having been deprived of its alkali is no benefit to vegetation. A great mistake therefore is often made by the farmer who says, My land does not want chalk, for there is plenty in the land. In all cases we advise the home farmer to have the land analysed, for it has been found that chalk was totally absent from the active soil, although chalk had been found but a little below the surface-If chalk is not entirely absent or worn out in the land there is often not sufficient for the wants of the plants, for many vegetable acids frequently require to be neutralised.

The evidence of want of chalk is a matter of great practical importance, and there is no evidence so reliable as that of certain weeds prevailing to the injury of crops, such as the corn marigold, sorrel, morgan, also a small weed locally called bunting, and prevailing especially on sandy land, the white-rooted couch, the twitch or water grass running on the surface, especially on strong heavy land, and also the black bent grass. All these denote the absence of chalk in the soil more or less, and practically it is impossible to keep the land clean-in fact, it is the decay of many of these weeds which leaves the injurious vegetable acids in the soil, and is really the cause of chalk being required on heavy land, and lime upon the light soils; still all crops require lime, as we have before stated. In considering the practical effect of chalk and lime, and believing, as we do, that in ordinary cultivation chalk will last twenty years, and that 10 tons of lime to be the equivalent, the chalk will continue to operate for a much longer time than lime; we therefore propose that 5 tons of lime should be applied at the end of every seven or eight years instead of giving the whole dressing at first. In the case, however, of farms, being quite out of chalk, and which is the case in various important districts, it is not practicable to chalk a whole farm or estate within a short period; therefore we have advised that an arrangement should be made with the tenant in occupation or home farmer to chalk or lime a given acreage every year, in order that within a reasonable time the whole of the land requiring it should be done, so that the letting value should be maintained or increased as circumstances occur. In the meantime, as fast as the rotation brings the fields in course for roots, it is well that about 20 or 25 bushels of screened chalk should be drilled with the arti-

ficial manure, in the same way as ashes are generally used. This will ensure a sound growth and increased weight of the crops, at least as far as turnips and all the Brassica or cabbage tribes are concerned, the exception being mangolds, carrots, parenips, &c., which will produce fair crops without chalk in the land, but much better crops when chalk or lime is present in the soil. These observations bring us to the point where some difference of opinion still exists—as to the cause of ambury or clubbed roots, to which turnips, cabbages, &c., are subject on certain soils and in certain seasons, the latter being often considered to be the cause of this disease of the roots of the plants; but this is not so, because we speak from a long experience in the growth of roots, and we assert most distinctly and advisedly that the absence of chalk or lime is the cause of this disease in the roots of these plants. Of course, during the decay and disease of these plants they will always be found infested with parasitic insects more or less, according to the weather, the time of year, the stage of disease, and other influences. Now, this fact of the presence of insects has raised considerable discussions amongst eminent theorists as to whether the insects are the cause of the disease or were only located there in consequence of putridity of the roots. We say the insects do not cause the disease, but are found there in consequence of it. We find that some theorists hesitate very much, and do not give a decided opinion either way; but we, together with some of the most practical men of the day, assert, as the result of our experience, that this disease, whether called ambury or clubbed root, never has been known to affect the root crops when a proper amount of chalk or lime has been found in the soil and ascertained by analysis. It has frequently been asserted that the disease is often found upon soils resting on chalk, or what is called chalk soils; but, as we have previously shown, this is a mistake or a delusion, because land resting upon chalk or rubble is frequently found to be entirely destitute of chalk or lime in the active or surface soil. tis said by the market gardeners that manure will prevent the club roots in cabbages, &c.; so it will sometimes if the town manure, consisting principally of coal ashes, is applied in large quantities, because this kind of manure contains more or less lime; but pure horse, cow, or pig dung, which contains but little if any lime, will not produce the same effect.

WORK ON THE HOME FARM.

Horse Labour.—On some farms where the land is dry and friable, and the land sown with wheat out of clover ley, it has been finished and in good order with no more than the usual labour of ploughing, pressing, harrowing, &c., and upon such occupations the home farmer has now only left the land where roots are being eaten off to be sown the first favourable opportunity. Upon the strong land, however, it will be some time before the wheat seeding can be completed. Under such circumstances where the land was attempted to be fallowed in the summer, or where fallow crops have been fed off on the land, the ground is not generally in a proper state of cleanliness to be seeded. Therefore, even if in a proper state of cleanliness to be seeded. Therefore, even if the land is in good condition as regards manure, the precaution should be taken of ploughing with skim coulter and followed by the presser, so that the roots of grass and weeds may be properly tucked under the furrow. The sowing is also of extreme importance in such cases, because we say that the wheat should be drilled at 12 inches between the rows, so that in the spring of the year the land may be properly horse-hoed in order to destroy the weeds and couch, or keep them under so as not to compete with the wheat plants. Another effect is the opening of the surface by the horse hoe at the same time not only giving vigour to the by the horse hoe, at the same time not only giving vigour to the plants, but destroying weeds started from seed in their infancy upon any strong land. The farmer will not be master of his position unless wheat is drilled at the wide distance. We also advise that at all intervals when the weather makes it possible for to effect any cleaning of the surface of land intended for potatoes, mangold, cabbage, carrots, &c., it should be done. We do not expect, however, to be enabled to burn any rubbish which may in raftering, scarifying, and harrowing the land be got together on the surface by the chain harrow, horse rake, &c., at this late period of the season; it may be carted away to heap and be valuable for purposes which we have often referred to in these columns when it becomes decayed. Our system has been for many years to continue cultivation of this kind as long as the state of the land renders it possible, and then to go on fallow-ploughing the land a good depth, and let it lie the winter ready to be cultivated with the scarifier, whether for barley after wheat or root crops, as spring ploughing is always attended with more or less uncertainty of results, whether the season proves wet or dry, the time of seeding, too, being always one of the most important factors in the

transactions of early and spring seeding of the various crops.

Hand Labour.—This is now the time of year for planting, because trees, whether of the firs for timber or underwood for various purposes, for wherever the plantations are of sufficient age and growth to pay for cutting, let the land be cleared of the crop of timber and planted again; for in the work of grubbing up and lifting the stumps and stools of the timber which has been cut the land will or nearly so be got in order for replanting, or for future cultivation, if it is so intended. We could now point

to many pieces of land upon gravelly and sandy soils which were comparatively worthless for cultivation when first planted, yet after bearing a valuable crop of Scotch firs cut and sold for railway sleepers, or in other cases where the larch firs have been way sleepers, or in other cases where the larch firs have been grown and cut and sold for hop poles, or left to become of larger dimensions. The land has been made valuable owing to the annual fall of leaves during growth, by accumulation of humus in the soil, and thus not only has the land been brought into cultivation but yielded also a valuable and profitable crop of timber, whilst the land has been preparing for future cultivation. In fact, this is almost the only way in which we have been enabled on various estates to make it answer for bringing poor thin soils In fact, this is almost the only way in which we have been enabled on various estates to make it answer for bringing poor thin soils into a condition for agricultural purposes. Threshing corn will now be going on, at least the portion of the crops which has been harvested in fair condition. In doing this we must consider the uses for which the straw and chaff will be required, for with such a deficient crop of roots as we have this year in most districts it will be of more than usual importance to preserve any straw required for feeding cattle in the best possible manner, not straw required for feeding cattle in the best possible manner, not only by properly stacking and thatching, but also by the use of some spice or flavouring materials strewed over it in the act of stacking. We recommend out straw as being preferable to all other for feeding cattle, as illustrated by analysis of its feeding properties. Now the root crop is so short it will serve to teach the home farmer or remind him of the propriety and advantage of giving a very small allowance of roots to the in-lamb ewes. It is too often the case when roots are plentiful that the sheep are given roots without stint, and with reference to the feeding of regnant ewes it has frequently been the cause of serious losses pregnant ewes it has frequently been the cause of serious losses both of ewes and lambs at yeaning time. Another important point in feeding the ewes is, that we have always found sweet straw better than hay, especially when the straw has been pre-pared for the purpose in one of the various methods adopted. Some farmers pulp roots to a small extent just sufficient to mix with and moisten the straw when cut into chaff; others merely cut the chaff, damp it, and add some spice. Some farmers use molasses or rough treacle to mix with the chaff; any of these mixtures answer a good purpose if they induce the ewes to con-sume straw in preference to hay.

MESSRS. CARTER'S ROOT SHOW.

On the 21st inst. Messrs, James Carter & Co. held their annual Exhibition of Roots in the Agricultural Hall, Islington, and not-withstanding the adverse season growers have had to contend with, the exhibits were both numerous and of general good quality. Most of the classes were well filled, and in some the competition was particularly close and good. Nineteen classes were appropriated to roots, and the entries in these classes numbered collectively over six hundred; the prizes ranging in value from £10

fectively over six hundred; the prizes ranging in value from £10 down to 5s.

The principal exhibitors were Her Majesty the Queen, H.R.H. the Prince of Wales, the Right Hon. Lord Clinton, the Right Hon. Lord Hastings, the Right Hon. Lord Warwick, Sir Wm. Farquhar, Sir Curtis Lampson, Admiral Sir G. N. B. Middleton, Sir Paul Hunter, Major Allfrey, East Barnet Local Board, Mrs. Morten (steward, Mr. Cave), Bedford Urban Sanitary Authority, Professor Buckman, R. Webb, Eaq., and Messrs. Hepburn & Son, Dartford. In the class for the best twelve roots of Carter's Prizewinner Swede upwards of 120 competitors appeared, many staging collections of excellent quality. The first prize was awarded to Mrs. Morten (steward, Mr. Cave), for a collection of remarkably even handsome specimens. In the four classes devoted to Mangolds, eight roots of the following varieties: Carter's Warden Yellow Globe, Mammoth Long Red, Intermediate, and Yellow Tankard-shaped, the premier prize in each class fell to Mr. R. Webb, S. Beamish, Esq. (steward, Mr. Beecher), Sir Paul Hunter (steward, Mr. Firman), and R. Webb, all of whom exhibited roots of superior quality. Two classes were appropriated to Turnips, twelve roots of White-fieshed and Yellow-fieshed respectively. In the White-fieshed class the honorary position was allotted to a collection from the farm of Her Majesty the Queen (steward, Mr. W. Brigginshaw). The roots were very symmetrical and of fine quality. W. L. Beale, Esq. (steward, Mr. G. Whitfield), was awarded the chief prize in the other class. Kohl Rabi was well shown by B. P. Harris, Esq., who gained the first prize in the class for nine roots of Carter's Imperial Green. Mr. R. Webb exhibited the heaviest and handsomest root of Carter's Improved Mammoth Prize Long Red Mangold, and accordingly was awarded the premier prize. The same exhibitor also received the chief prize in Prize Long Red Mangold, and accordingly was awarded the pre-mier prize. The same exhibitor also received the chief prizes in misr prize. The same exhibitor also received the chief prizes in the classes for single specimens of Mangolds and Swedes of Messra. Carter's approved varieties. The silver cup value £5 offered for six roots of Carter's prize Mangold, any variety, grown upon sewage farms only, was awarded to the Eton Local Board (steward Mr. C. Tough), for an even and good collection. The five-guinea cup offered by Messra. J. Gibbs & Co., 16, Mark Lane, for the best collection of roots grown from Messra. Carter's seeds with Messra. Cibbs' manures was obtained by T. H. Farra Rag (steward Mr. Gibbs' manures, was obtained by T. H. Farrar, Esq. (steward, Mr. S. Stevenson), with a fine collection; and the silver cup of equal value, offered by Messrs. Ohlendorff & Co., 15, Leadenhall Street,

under similar conditions, was adjudged to N. Parry, Esq. (steward, Mr. F. J. Holmes), also for highly meritorious roots. Among Messrs. Carter's miscellaneous exhibits were sixty-two varieties of Turnips grown in their trial ground all good and true, and large heaps of the Champion and Magnum Bonum Potatos, the former of which produced in 1878 nine to twelve tons per acre, and

the latter six to eight tons per acre.

The whole Exhibition proved a great success, and Messus.

Carters are deserving of credit for their energy and confidence in holding their exhibition in such an unpropitious season.

"ANY OTHER VARIETY" CLASSES.

Wn fear that poultry fanciers are wont to be somewhat change-able in their fancies. There are certainly breeds of undeniable excellence which always hold their own and probably always will do so, but there are others of great beauty and some usefulness which have their day and then are neglected. We have often expressed our opinion that what are called "paying" classes at shows have had much to do with the almost extinction of some varieties, which have been relegated to the Any other variety class varieties, which have been relegated to the Any other variety class simply because they were not entered in large numbers, and there often passed over from the predilections of particular judges for particular sorts, or from the sheer immensity of competition have gone out of notice and been lost, or only survive in a degenerate state from having been long bred in-and-in by one or two fathful delivers. admirers. We must own to a considerable improvement of late in this respect. Through the exertions of single fanciers or of clubs of fanciers several kinds now have their class at every moderatesized show which a few years ago took their chance in the general refuge for the destitute. We can remember when the French breeds refuge for the destitute. We can remember when the French breeds emerged from it; then Black Hamburghs, then Malays, then Leghorns, then Andalusians, and now Sultans are doing so. In the case of some of these breeds the particular class was only a revival, for in former days Malays and others had them but again declined. There are still, however, many beautiful kinds which we seldom see out of a variety class. How often in a report of a show, after elaborate criticism on the toes of the winning Dorkings and on the pencilling of the Brahmas, do we read, "the Any other variety class was large and interesting," with little notice of the less-known commants of its pens? We purpose from time to time to devote a few articles to the

description of some of the breeds which are only seen in such classes, which either for their beauty or good qualities we should classes, which either for their beauty or good qualities we should like to see more cultivated. Foremost among them is a breed on which we will now give a few notes—viz., Buff Polish, or, as it is called in France, Padoue Chamois. It is by no means a new race, but one which we have been wont to see now and then from our childhood in variety classes at Birmingham and elsewhere. In the original "Poultry Book" by Messrs. Wingfield and Johnson was a very pretty illustration of these birds which has not been reproduced in Mr. Tegetmeier's work. Perhaps it was somewhat fattering: at least, we have never seen heap so well marked. reproduced in Mr. Tegetmeier's work. Perhaps it was somewhat flattering; at least, we have never seen hens so well marked, though some cocks at the great Paris Exhibition of 1878 almost came up to the standard. The general characteristics of the breed resemble the rest of the Polish family. It is said to have been produced by a cross between the Golden-spangled and the now almost extinct White Polish. The most perfect type of plumage would be in the cock the golden part, as in the Golden-spangled, with white markings substituted for the black, though such a bird we have never seen. The hen should be of a deep buff colour with white spangling, though the hens we have seen are further than the cocks from at all approaching this standard. The breed is very beautiful, even when specimens of it fall far short of

this ideal excellence.

It is by no means uncommon in France, where a beginner would have a good chance of procuring good birds at what in England we consider moderate prices. There seems a general tendency in it towards mealiness—at least, the birds now shown in Ragiand are almost always too pale in colour; indeed, some which we lately saw, and which we believe are descended from some first-rate French stock imported last year, were so also. We should therefore advise that recourse should be had to the Golden spangled in any attempt to improve the breed. A cross with a condition of the colden at the colden spangled in any attempt to improve the breed. spangled in any attempt to improve the breed. A cross with a good Golden strain ought to improve the form as well as the feather, for in symmetry of crest it certainly by no means comes up to the three better-known varieties. It certainly has the elements of being one of the loveliest of the tufted fowls we possess; and we believe that only a little time and trouble is needed, in a tolerably warm and dry climate, to bring it to a state of perfection which could not fail to carry all before it in "Any other variety" classes.—C.

BIRMINGHAM CATTLE AND POULTRY SHOW.

THE managers of this important agricultural association are to be congratulated on the support which has been accorded to them by intending exhibitors at the thirty-first annual Show, which opens on the 29th November.

The entries of cattle are exceedingly large, and the Show being

held before the London one, they will no doubt be all present, and should by all means be seen in their first bloom after leaving home. Sheep and pigs are a fair show, and the roots, contrary to general expectation, will form the largest collection ever seen in Bingley Hall.

£2700 is the amount of prizes given this year for meritorious specimens in almost every branch of agriculture, including the too specimens is almost every branch of agriculture, induting the too much neglected poultry, which is here seen in perfection. Turkey cocks are found weighing close on 40 fbs. each, Geese 50 fbs. the pair, Ducks over 20 fbs. the couple, fowls up to 12 fbs. each. The breeding of profitable poultry properly encouraged should effect great improvements in the specimens usually seen in the farmwards of the kingdom.

The Hall has been thoroughly put in order for the Show; the gashttings are entirely new, twenty-four new skylights have been put in the poultry bay to afford additional light, and to further secure this the new wire pens will be used throughout.

The applications for space from implement makers are unprecedentedly large, so much so that many not exactly legitimate exhibits are declined altogether, and others receive only a third of the amount applied for.

Most satisfactory arrangements have been made with the railway companies as to excursion trains from all parts; and with favour-able weather we look forward with confidence to the issue of the

1879 Show.

The judging commences on Saturday the 29th inst., when the charge for admission is 10s., except to life members, who receive free admission to the whole Show, in addition to other privileges.

Monday December 1st, when the admission is by subscribers' tickets or payment of 5s., is considered the ladies' day, when the slies of the midland counties are present in large numbers; for Tuesday and Wednesday (1s. days) numerous excursion trains are announced; and on Wednesday and Thursday evenings the working classes and children will be admitted at the reduced rate of 6s. after 5 P.M.

THE CRYSTAL PALACE POULTRY SHOW.

Houdans.-Cocks of this breed numbered twenty pens, though Houdans.—Cocks of this breed numbered twenty pens, though two or three were empty. First (Stratford), which won and well deserved the cup, was a fine cup bird, stout in build, very sound in feet, nice creet, very good and not exaggerated comb, and very goed in colour. Second (Wilson) was a large thick-set bird, very nice in colour but bluish in leg, scarcely correct in comb, and rather small in creet, which will improve yet doubtless. Third (Ogden) was good in comb, middling in crest, nicely mottled, good feet, large, well made. 931 (Meredith) a large bird; 934 (Mrs. Lane) very broad built, good in crest, and poor in comb; 928 (Rintoul) good in crest and comb. Hens (eighteen) were a good (Rintoul) good in crest and comb. Hens (eighteen) were a good class. First (Stratford) was a very large hen, beautifully and correctly mottled, very good in creet, and sound in feet; she has spurs. Second, belonging to the same exhibitor, was very evenly mottled, but darker in plumage than first; sound in foot, but with blue legs, fine in crest, and very large and good; in very fine plumage. Third (Morris) was a good heavy hen, sound in feet, good in colour, and fine in crest; 948 (Meredith) good in colour, sisse, and crest, but with one bad foot; 950 (Thomas) light in colour, but very good in creet; 961 (Howard) a very good hen, large, good in colour, splendid creet, and sound feet. Cockerels numbered twenty-four pens. First (Nicholls) was a good style of bird, good claws, nice comb and creet, and fair in size; second numbered twenty-four pens. First (Nicholls) was a good style of bird, good claws, nice comb and crest, and fair in size; second (Hamlyn) was very good in size and colour, very good in feet, nice crest and comb, and a cheap bird; third (Ogden) was large, fine in crest, good in colour, limb, and claw, but scarcely the thing in comb; fourth (Blair) had nearly white legs, was good in crest and comb, fairly good in colour, and of nice size; 970 (Lane) was white in crest; 978 (Brooke) dark, good, will make a fine bird; 988 (Harrison) good in size and fair in crest. Houdan pullets were the largest class of this variety, counting up thirty-two pens. First (Thomas) was a very good pullet, fine in leg and claw. were the largest class of this variety, counting up thirty-two pens. First (Thomas) was a very good pullet, fine in leg and claw, eplendid crest and beard, and good colour; second (Wood) was large, good in crest, fine in colour, shape, legs, and feet also good; third (Stratford) was a very good globular-created bird, good in colour, of nice size, good toes, but rather too blue in legs; fourth (Pearce) good in shape, also in legs and feet, rather small, and white in crest; 995 (Pattinson) pretty crest, good colour, nice shape, and sound feet; 997 (Thomas) good, very pretty crest; 1006 (Stratford) rather dark, good in size and claws, nice creet, but bluish leg; 1017 (Wood) and 1020 (Hall) good pullets. The Houdan classes contained many really good birds.

*Crève-Cœurs.**—The Crèves were not so numerous as the Houdans,

Crève-Cœurs.—The Crèves were not so numerous as the Houdans. mor yet were they equal in quality as a whole. In cocks (nine in number) first (Mackwell) very good in size, shape, and comb; good in plumage, and a good broad bird, but not large in crest. Second (Wilkins) was good in comb, fair in crest, and large; but second (Willis) was good in only, lair in cress, and large, but his appearance in the show pen was not improved by one spur growing downwards. Third (J. Ward) was large, and his crest all on one side. We much preferred 1028A (Malden), a fine large bird, in fine condition, and good in head characteristics. The class, as a whole, was rather poor. Hens were better, numbering

eighteen. The cup bird was good and very close in crest, very glossy in plumage; a large and very good bird, although she had bluish legs. Second (Ward) was splendid in crest, large, and very broad; in fact, larger than the winner, and quite equal, we thought, in other respects, excepting not being so glossy in plumage. Third (Ogden) was large, fine in crest, and good in shape, but dullish in colour; 1029 (Jackson) was a good creeted hen; 1081 (Calvert) was rather small, but fair in crest; 1085 (Wood), 1087 (Ward), and 1045A were all good hens, good in crest and size. In cockerels and 1950A were all good hens, good in crest and size. In concereis, (fifteen) first was a clear win, being splendid in crest, good in comb, very good in style, and in very fine condition, although rather small. Second (Hall) small in comb, close-fitting in crest; a stout well-built bird. Third (Ward) good in crest, rather large in comb; a large and glossy bird. 1054 (Williams) good in crest; 1060 (Clayton) very large.

Pullet warm of fire clear of fifteen. First (Hall) had a warm

Pullets were a fair class of fifteen. First (Hall) had a very close globular crest, glossy plumage, and was a very good large bird; second (Chadwick) was large, good in crest and in shape; third (Calvert) was a nice-shaped bird, but rather small in crest; 1066 (Burrell), 1070 (J. Ward), and 1078 (Fowler & Co.) were all good.

Game.—Black Red cocks (fifteen) were a good lot upon the whole. First (Hon. and Rev. Dutton) was not yet in full feather, but a very good bird, beautiful in colour, and good in head; second but a very good bird, beautiful in colour, and good in head; second (Pratt) was a good long-headed bird, bright in colour, and of nice style; third (Bandall) good in head and colour, tall, and reachey; 1242 (Pope), 1237 (Colgrove), and 1248 (Dr. Cameron) were good birds; 1240 (Matthew) good in colour and shape, but not well through moult yet. In cockerels (twenty-one) first-and-cup (Pope) was the Oxford cupwinner, a splendid bird, very good in head, colour, and style, and very leggy; second (Matthew) was a very leggy bird, capital in colour, and splendid head; third (Gray & Stephen) good in limb, good head, and nice style; fourth (Walters) good in head excepting eves. and fine colour: 1246

(Gray & Stephen) good in limb, good head, and nice style; fourth (Walters) good in head excepting eyes, and fine colour; 1246 (Bellman) very good style, 1248 (Mason) nice colour, 1258 (Nelson) good and nice style, and 1259 (Pratt) good in colour and shape.

In hens (fifteen) first-and-cup (Pope) had capital legs, very good in head and eyes, nice shape, and good colour; second (Sales) was a good-shaped bird, nice colour, a well-made bird, with a very good eye; third (Staveley) had dark eyes, but was very good in colour, leggy, and of good shape. The highly commended hens and several others in this class were very good birds. In pullets (twenty), first (Matthew) was a grand-headed bird, good sound colour, and fine style; second (Voisin) was good thoughout, fine in colour, and in head; third (Caton) was a nice well-made pullet in splendid condition; fourth (Shore) was good in colour, nice style, and good tail; 1290 (Lyon) a very good pullet, fine in shape; 1800 (Pope) good, as were the other mentioned birds.

In Brown Red Game cooks (thirteen), first (Garnett) succeeded in carrying off the cup for the best Game cook in the four classes. He was good in colour, though just a trifle dark on the breast,

in carrying off the cup for the best Game cock in the four classes. He was good in colour, though just a trifle dark on the breast, splendid in head, good face and eyes, and good in shape. Second (Matthew) was a good one, very good in shape, and a splendid head, though his colour was scarcely to our taste, being too dark; third (Maynard) very good in head, gipsy face, and sound in colour, though dark on the breast; 1803 (Wolff) was good in shape and very nice in colour; 1805 (Martin) very good in head and colour; 1809 (Sanders) a nice laced breasted bird; 1814 (Cameron) a very good bird with a splendidly laced breast.

Cockerels were a large class (twenty-five), and the cupwinner (Fenwick) was in nice condition, of very good colour and with

(Fenwick) was in nice condition, of very good colour and with finely laced breast, very good in face and eye; second (Matthew) (Fenwick) was in nice condition, or very good colour and with finely laced breast, very good in face and eye; second (Matthew) was darkish in colour but good in shape, with a fine head and good gipey face; third (Garnett) was dark in colour, but very well laced on the breast, fine in head, face, and eye, and in first-rate condition; 1815 (Wolff) a good bird; 1818 (Gray & Stephen) nicely laced breast; 1820 (Mercer) very young, but good in quality and very good face; 1822 (Martin) out of condition but beautifully laced on the breast, very good in colour, and good face and head; 1830 (Riley & Cooper) and 1838 (Braithwaite) were good birds. In hems of this variety (eighteen), first (Matthew) good in size, beak, and comb, fine gipsy face, well made and good in colour; second (Voisin) nice in shape and good in head, fair hackle, a fine strong made bird; third (Mather) a very good bird excepting her coppery hackle, in very fine plumage; 1368 (Cannon) very highly commended, splendid in hackle and very good head; 1342 and 1843 (Warner and Hodgson) both good birds; 1866 (Fenwick) also good. In pullets (twenty-six), first (Fludyer) a grand bird, fine in head, eye, face, and beak, and splendid in hackle; second (Matthew) also a splendid bird, and very similar; third (Webster) good shape, very fine hackle, and good head; fourth (Garnet) nice head, good hackle, and very good eye; 1860 (Ward), 1876 (Taylor) good, and 1877 (Braithwaite) very good in hackle.

nackie.

Duckwing cocks were a small class (nine). First (Matthew) was a grand bird, splendid in colour, fine in style and condition; second (Harley) very good in colour and style; third also a good bird; 1885 (Martin) a good bird. In cockerels of this breed (thirteen entries), first (Dr. Cameron), a very fine-shaped bird, not quite perfect in colour but a good bird; second (Fell) very

good in shape, head, style and colour; third (Garnett) very good colour; 1898 (Staveley) very good in colour and head; 1400 (Freek) good. In hens (eight) Mr. Matthews won very properly with a hen in very good hard feather, good in head, eye, and comb; (Freek) good. In hens (eight) Mr. Matthews won very properly with a hen in very good hard feather, good in head, eye, and comb; second (Thomas) handsome colour, good in shape, fine head but dark eye; third (Kitson) coarse in comb, good in colour, and good in eyes; 1407 (Staveley) very good, especially in colour. In pullets (twelve), first (Sales) very tight in plumage and good all round, excepting a darkish eye; second (Matthews) was also darkish in eye, but a well-made bird, good in colour, and with a capital long head; 1419 (Hollingworth) and 1421 (Harley) good pullets. In the four classes for Game of any other variety all are Piles; and in cocks (six), first (Fitzherbert) was a willow-legged bird, fair in head and plumage; second (Walker) a yellow-legged bird, good in shape and very leggy; third (Cannon) another yellow-legged one, good in shape and nice in plumage.

This was not a very good class, but the next for cockerels (ten) was better. First-and-cup (Lyon) a splendid yellow-legged bird, long in head, very leggy, and a fine bird; second (Colgrove) a fine handsome bird, yellow-legged bird in very good plumage; the other honourably noticed birds also good. In hens there were only four entries. First (Walton) was a good shaped and good colourred hen; second (Colgrove) a large hen of good colour; third (Lyon) dark in eye, rather pale on the breast. In pullets (ten) all were yellow-legged. First (Colgrove) a nice pullet, though we thought her a trific clumsy; second (Colgrove) a good bird with a nice head; third (Walker) a good shaped bird.

In the five-guines Selling class, first (Maynard) were Black Reds; second (Fenwick) Brown Reds; third (Colgrove) Piles. In Malay cocks (fourteen), first-and-cup (Mercer) was a good tall, leggy Black Red cockerel, very fine, large, and in good plumage; second (Maring) large, and in good condition; third (Michael); good bright-coloured cock in good condition; third (Michael); good leggy bird, darker in colour; third (Lecher) fine, very large,

good bright-coloured cock in good condition; 1479 (Walton) and 1488 (Nicholls) were capital white cocks. In hens (fourteen), first (Burnell) was a good large lightish-coloured hen; second (Mercer) good leggy bird, darker in colour; third (Lecher) fine, very large, leggy, very good head, and the fashionable colour; 1498 (Joint), and 1494 (Lowe) were also good.

Legkoras.—In Brown cocks (fifteen) first (Richardson) was a good-coloured bird, smart, fine in comb and ear, and good yellow leg. Second (Fowler & Co.) had a large thumb mark on his comb; in other respects a very nice bird. Third (Fowler) rather small, good ears, and a very well-formed comb; nice colour. 1591 (Philcox) good. In hens (also fifteen) first (Gibol) was a very good bird, capital in comb and lobe, and good yellow legs; second (Dr. Foster) was good in colour, nice comb and ears, nice size and legs; third (Philcox) was yellowish in lobe, very good in comb, and of good shape and colour; 1604 (Sleigh) and 1615 (Philcox) both good. In White cocks (fourteen) first-and-cup (Mrs. Troughton) was a stylish bird, capital in comb, and good ears and legs; second (Bradbury) was neat in comb, a good white, nice-shaped earlobes, and a nice-shaped bird; third (Fowler) good in comb but rather roughhab in ear. In hens (sixteen) first (Clemenson) was very good, legs good, very pure white, and capital comb and ears; second (Gibb) good in comb and lobe, bright yellow legs; 1681 (Gibb) capital in comb and lobe.

**Andalusians and Misorcus were classed together. In cocks comb and lobe

good in comb and lobe, bright yellow legs; 1631 (Gibb) capital in comb and lobe.

Andalusians and Minorcas were classed together. In cocks (twenty-three) first-and-cnp (Mrs. Wilson) was a very fine Andalusian, well laced, large, and fine comb and limb; second (Elaton) was a Minorca, good in comb and earlobe; a fine bird. Third (Boissier) again a Minorca; a good large bird, but a trifle imperfect in comb. 1646 (Elston) was a good Minorca; 1647 and 1649 (Stephens), 1651 (Mrs. Cross), and 1656 (Brooke) were very nice Andalusians; 1658 (Harwood) a very good Minorca, capital comb and lobe. In hens (nineteen), first (Burton) was a Minorca, splendid in comb and ears; a fine large bird. Second (Stevens) an Andalusian; a good large bird, nice in colour, and good in comb and earlobe. Third (Mrs. Wilson) was also a very good Andalusian. 1674 (Brewer) and 1681 (Briggs) were very nice Minorcas; and 1684 (Mrs. Troughton) a good Andalusian, rather small in comb. In old Sultans (twelve) cup (Atkinson) were fine in creat, and a very good pair. Second (Damant) good; the hen better than the cock. Third (Mrs. Christy) cock very good crested and well-feathered pair; second (Nicholson) good in creat; third (Mrs. Christy), the cockerel better in shape of creat than the pullet; fourth (Rev. J. P. Wright) a nice pair, the pullet rather small and young.

The Selling classes contained many very cheap birds, and in these a great number changed owners. We noticed many birds.

The Selling classes contained many very cheap birds, and in these a great number changed owners. We noticed many birds that would have been very cheap at double the price, not merely amongst the prize birds, but also amongst the commended and highly commended birds. To particularise amongst these would be an invidious task.

Game Bantans were numerons and good, though many of the best are unnoticed. In Black Red cocks (thirty-five in number)

first-and-cup (Walton) was very fine and rich in colour, smart, fine in head, and very leggy; second (Hore) was rather large, good in style, and very long on the legs; third (Brownlie) nice in colour, good in head, and very smart; fourth (Stretch) was small and good; 2178 (Anns) very good style, 2185 (Addie) very smart and good in head, 2191 (Duncan & Kennedy) rather large, 192 (Nelson) a good bird, and 2203 (B. Bavis) good. Hens were good, and the winners were all good. None of the other Game Bantam classes numbered so many nens as the Black Beds, but there were classes numbered so many pens as the Black Reds, but there were first-class birds in each class. In Japanese first (Mrs. Woodcock) first-class birds in each class. In Japanese first (Mrs. Woodcock) were small Whites, in very fine feather and condition; second nice Cuckoos; third (Heald) good Whites; 2846 (Heald) also good White; 2849 (Mrs. Brassey) good Blacks; 2851 (Thorpe) leman, good. In Sebrights only eight pens were entered; all Silvers excepting one, and all noticed. First (Burnell) a splendid pair, very clear, and distinct in lacing; second (Leno) a capital pair of Golden; third (Stephens) Silvers, very finely laced; the other five pens were all very good, and worthy of their cards. In the Variety Bantams (ten) first (Crowther) were handsome little clean-legged rose-combed Whites; second (Duckworth) very pretty Cuckoos or Scotch-Greys; third (J. Wood) White-booted, good and very clean; 2874 (King) very good White-booted.

All varieties of Ducks were well represented, the larger sorts being very good in size, and other points also; the ornamental varieties being very beautiful.

HAMRITRGHS.

HAMBURGHS.

These birds held their position well; the five varieties mustered over 150 pens. The first (Bracewell) Golden-spangled cock was a good all-round bird with a capital honestly shown comb; he would stand with his tail wry in the pen, but this by no means proves that it was not really straight. Second (Blakeman) a nice smart bird with wonderfully spiked comb, good colour but breast too much laced. Third (Crosthwaite) neat in comb, like a pencilled bird, with a fine outline of form; his tail hardly fully grown yet. 1088 (May) very highly commended, a nice bird. Hens (Jackon) first-and-cup well shown, and good all round; second (Duckworth) had larger moons than the first, but was not in such condition; third (Bracewell) smaller spangling but glossy, and ground colour rich and good. Silver-spangled cooks were the smallest Hamburgh class. The cup (Beldon) cockerel was a most perfect bird in every point, his neck hackle perfection, unfortunately he has lost a sickle; second (Cannon) a bird with a good comb and nicely spangled tail, his lobes not very smooth. The first (Ashton and Booth) hen was the most evenly-mooned bird we ever saw, and her moons the right size; second (Beldon) apparently a pullet with a wonderful green gloss on her spangling; third (Beldon) a her which we thought equal to the second.

The first (Morris) Golden-pencilled cock was of the right colour in general but too brown in tail, and his tail small and mean; second (Duke of Stytheyland) a few better hid from the second.

in general but too brown in tail, and his tail small and mean; second (Duke of Sutherland) a far better bird to our fancy with the most beautifully laced tail we ever saw; third (Bell) good in carriage and fair in colour, but with a bad, and we suspect trimmed comb. The first (Beldon) pullet was very perfectly peacilled, some would think her bars a little too broad, but we do not and she has that unusual accompaniment of good pencilling and a really clear hackle; second (Bell) had a good comb and black marking though it might be finer; third (Tickner) very finely

pencilled.

Silver-pencilled cocks numbered eleven, not remarkable in uality. First (Bracewell) had a nice honest comb (indeed quality. First (Bracewell) had a nice honest comb (indeed throughout these classes a great improvement is taking place in this respect), good carriage and well-laced tail; second (Snell) a fair bird all round, comb not so good as the first; third (Beldon) too yellow. None were noticed beyond the prize birds. Of the hens first and second (Beldon) were as like as possible and well barred; third (Kilby) good in comb, too squat a bird. Black cocks made a very large but not a very good class. First (Kellewsy) a lovely bird in carriage and extremely green in gloss; his comb strangely perfect; second (Copeman) fairly green, very good is lobes; third (Gilroy) a fair bird which did not stand well. The fint hen (Kellewsy) hen a bird of fine shape in the pink of condition; hen (Kelleway) hen a bird of fine shape in the pink of condition; second (Gladstone) glossy and good in shape, not good in comb; third (Painter) good in form, too blue in colour; we much admired 1221 (Garnett), and should have put her second.

Any other distinct variety.—This was a fairly interesting class;

Any other distinct variety.—This was a fairly interesting class; it is a great pity that the names of the breeds are not prited in the catalogue. First (Swinburne) came La Flèche chickens, a fine pair; second, Miss Hubbarb's grand Scotch Greys; third (Holmes) vary good Silkies. It seems most strange that at a show of the size and importance of the Palace there should not be a class for this variety. Next to them were another very nice pair of the same breed. Among others were shown two pairs Courtes Patter, some Indian Game, and a pair of Blue Bredas from the yards of Mr. J. C. Fraser, who seems great in nicking out curiostities.

Mr. J. C. Fraser, who seems great in picking out curiosities.

The basket show was an interesting one considering the short time that the competition had been announced; the collection of baskets, about thirty, was very good. The Judges went in for simplicity of construction; we regretted that one or two ingusious novelties did not take their fancy. First went to Mr. G. W. Hesshall of Gorton, Manchester, for a round lined basket with two handles, and half the top of close work; its price &. 6d. Second to Mr. R. Stevens, basket maker, Bracknell, Berks, for a simple handleless round lined basket; price &. 6d., and cheap too. Third to Mr. W. T. Elmore of High Street, Leicester, for a very pretty little double basket, price 10c. 6d., and not at all dear for the work in it. Hints might be taken from many of the other baskets. We thought one shown by Messrs. Boulton & Paul by far the most ingenious in the Show. It had a well-arranged place for feeding birds from without, and might with some modification be made useful for exporting birds. There certainly must be something in it, for we saw that it was bought by so practical a fancier as Mr. S. Matthew. Good double baskets with single fastening came from Mr. G. P. Pointer of 80, Goswell Road, better perhaps in design than in finish. A hint, too, we took from one from Mr. Salter of Hemel Hempstead. The opening part of the lid was hinged on a piece of wood, giving it much firmness. We hope that before the next Palace Show basket makers will have time to think over the requirements of exhibition baskets, and produce some really practical improvements. The Poultry Club also promises for next year liberal prizes for the best coops or pens for the export of poultry.

Sales were not by any means so good or so numerous as in many years, still some are worth recording. Mr. R. A. Boissier's cup Silver-Grey Dorking cockerel was claimed for £20; his first-prize hen of the same breed for 12 guineas. Mr. Sharpe's wonderful Partridge Cochin cockerel for £63. Mr. Turner's cup White Cochin hen for £18 7a. 7d. Dr. Snell's third White Cochin hen for 10 guineas. The Duke of Sutherland's second-prize Golden-pencilled Hamburgh cock for 10 guineas; and Mr. Howard's cup

Rouen Duck for £13.

CANARIES AND RED MITES.

In reply to questions that have been submitted, we may state that Canaries are more liable to disease when they are tor-mented with red mites. The vermin troubles young birds more when in their first or nestling feathers than they do old birds. We have often gently approached the cages where young birds have roosted, and with the aid of a lighted candle seen the mites running in and out of the birds' feathers "like dogs in a fair," and running in and out of the birds reachers "like dogs in a tair," and noticed the poor birds shiver and tremble as it were with the irritation caused through the vermin annoying them. Young Canaries are mostly troubled about the wings and along and betwirt the butt ends of the pinion feathers. The birds will show traces of but ends of the pinion feathers. The birds will show traces of the vermin along the webbing of their flight feathers, which will appear spotted with small grey specks. Young Canaries much infested in their nests rarely make strong birds, and many a healthy brood of young birds dwindle away through the tormen-tors, which drain the young birds of their blood, and weaken the hens so that they become restless at roosting time, and either cause their offspring to die by being sat upon too closely, or otherwise not being kept sufficiently nurtured. When young birds in the nest become pale in their mouths and crops and bear a sickly the nest become pale in their mouths and crops and bear a sickly hue, in most cases it is brought about through vermin. Changing the old nests for fresh ones is the best remedy to keep the young if vermin are about. If confident the birds are free from the enemy, we would prefer the birds being reared in the nests the parents had prepared, for as a rule the birds do much better when they are not meddled with. Vermin not only secrete themselves in the cages, but at times small clusters may be found about the sides and more especially the necks of the food fountains. As to setting traps, we have tried hollow perches and placed shallow vessels with water beneath where the birds are likely to roost, in each of which many vermin may be caught, but still, like flies, there are always many more to supply their places. We once heard a fancier remark, "I have the red mites so numerous, I think they are great-grandfathers in four and twenty hours!" We do not place much faith in the above ingenious modes of capturing them, for whilst so doing we are only prolonging the misery of the birds by allowing the vermin nightly to weaken them. The most effectual way is to remove the birds away from the infested most effectual way is to remove the birds away from the infested cages, which should afterwards be effectually cleansed as described in the Journal, page 262. The walls where the cages hung must likewise be looked to. The mites may not be got rid of at once, and perseverance is necessary. It may be afterwards ascertained if the birds are still troubled with the pests by throwing a white linen cloth over the cage at night time. If there are any about the cage it will be next to a certainty that upon examination next morning some of the vermin will be found adhering to the cloth. Whilst at the recent Norwich Bird Show we had a very interesting discussion upon the subject with a gentleman deeply interested in the bird cause. We came to one opinion as to how the Canary bug or red mites were brought about, but how to prevent them was another matter entirely. We informed him that we had in numerous instances seen young featherless birds in their nests completely infested with the vermin in their ears and nostrils, but we were surprised when he told us that in several cases of post mortem examinations of birds the presence of red mites had been clearly traced to the pericardium of the heart.

This being the case there is no wonder at so many deaths occurring and giving previous signs of inflammation. The subject is worthy of further investigation.—G. J. Barnesby.

VARIETIES.

WE are glad to see that railway companies are beginning to see the benefit which accrues to them from poultry and Pigeon shows. The Midland Company send round circulars before great shows inviting exhibitors to send birds by that line, which we believe can be recommended. The L.N.W.R., too, is advertising the hours at which special through vans from the north to Birmingham will leave the greater stations.

— An Australian agriculturist writes as follows on the relative value of Shorthorn and Hereford cattle, "Reared under exactly the same conditions, and fed side by side on the same pastures, an excellent opportunity is afforded for contrasting the qualities of the various breeds of cattle, the test being an exceedingly fair one, as no hand feeding is given, unless possibly a little hay thrown on the pastures for a few weeks in spring, and no animal ever being in a house or shed till driven into the slaughter house. The two favourite breeds are the Shorthorn and Hereford, and there can scarcely be a doubt but that the latter is the most valuable. It is hardier in constitution, and stands the weather better than the thinner-skinned Shorthorn, holds the fiesh and internal fat longer, and recovers condition quicker in spring, while being quite as easily fed and attaining as heavy weights at quite as early a period of its existence."

The Exhibition of cage birds held in conjunction with the chrysanthemum Show at Southampton on the 18th and 19th inst. proved a great success. In no class throughout the schedule were there any blanks, and there was keen competition, notably in several of the canary classes, the Belgian, crested Buff Norwich, clear yellow or buff, ditto, and in British birds (blackbirds, thrushes, and starlings), and any other variety of the same (the latter a most interesting though mixed class). The special prize presented by Mr. R. Parker, J.P., for the best bird in the Show was deservedly awarded to a glossy starling exhibited by Mrs. W. C. Drummond. It was a lovely bird, of rare plumage and perfection of growth, and formed a great attraction. Mr. Walter Billett, High Street, had the superintendence of the birds, and the Show Committee consisted of Capt. Gibbs (Chairman), and Messrs. G. Billet, E. Chamberlain, W. Knight, G. T. Pope, W. H. Squibb, and H. Young. The Judge was Mr. F. W. Wilson of the Crystal Palace.

— We often have regretfully to notice the decline of the interest in poultry and Pigeon shows taken by the general public after they have become established institutions for a few years. We have been sorry to receive a fresh instance of this in the statistics of the money taken at the door of the late Oxford Show. At the first Show held there in 1872 the receipts were about £147, at the last £56.

— THE CHEESE AND BUTTER FACTORIES OF CANADA.—
From the official returns published by the Dominion Government, it appears that the quantity of cheese exported from the Dominion rose from 4,503,870 fbs. in 1869 to 89,871,189 fbs. in 1878, being an increase of 84,867,769 fbs., or not less than 774 per cent. in nine years. The value of the cheese exported in 1869 was 549,572 dols., while in 1878 it was 4,121,801 dols., an increase of 650 per cent., representing an average fall of about 14 per cent. in the price of the commodity. In 1869 the quantity of butter exported was 10,858,268 fbs.; in 1878 it was 18,504,117 fbs., being an increase of 2,650,849 fbs., or 24½ per cent. The value of the butter exported in the earlier year was 2,843,270 dols., against 2,474,197 dols., an increase of 5½ per cent., showing that the average price of butter was about 15 per cent. lower. Of these two articles of dairy produce Great Britain took the bulk. Thus in 1878 she bought 11,401,165 fbs. of butter and 87,648,008 fbs. of cheese from the Dominion. This vast increase in the cheese trade is due to the development of cheese-making under the factory system. It has become the practice now for farmers within a certain radius to send their milk to central establishments where the manufacture is carried on wholesale. Canadan farmers discovered only a few years ago that there was a great advantage in the way of economising labour and manufacturing expenses to be gained by clubbing together. It was no longer back than 1874 that the quantity thus turned out began to exceed 20,000,000 fbs. in a year, since which time the amount has been almost doubled. Factories are now in operation in nearly every section of the province of Ontario or Upper Canada.

— CATTLE plague, according to the current number of the "Veterinarian," is reported to have existed during the month of October in the Governments of Bessarabia, Volhynia, Ekaterineslav, Podolia, Taurida, Kherson, and Petrokoff, in Russia. The disease is also reported to have appeared in Russian-Poland, in the neighbourhood of Lubtenitz, on the Silesian frontier of Germany. In Austria cattle plague has broken out in the Government districts of Littai and Stangenplane, in Carniola; it is also

said to have existed in two or three villages near Rugusa, in | apiculture, I am quite satisfied with the hives I have long used.

NEW HORIZONTAL OCTAGON HIVE

I FROMISED to give your readers an account of Mr. Paterson's success with his new hive. I would have done so sooner, but a number of important engagements came in the way. I mentioned in my first communication that the swarm which he turned out of their comfortable quarters in the month of April, while snow still lay on the ground, was the weakest in his apiary, and I predicted all manner of evils in consequence. The season, the swarm, and the novelty were all against him; but, like all true inventors, Mr. Paterson was not to be daunted.

As I mentioned in my former article the bees at once took to their new abode, and commenced work with a will. As the month wore on the appearance of brood was most encouraging. shape of the frames and that of the clustering bees coinciding so exactly greatly favoured the hatching process, and before July had well begun several frames had to be added. By the end of July the hive was quite a sight, and the merry hum of the bees as July the nive was quite a sight, and the merry num of the bees as they went cut to their work in crowds gave full proof of the health and prosperity that reigned within. It was soon necessary to form an artificial swarm, which in this wretched season and at an altitude of 600 feet above the level of the sea was a thing to be spoken of. In the course of a month the swarm had got along-side the parent hive, and if there had been a longer season I am side the parent hive, and if there had been a longer season I am not sure but that it would have outstripped it. For this, too, there was a reason. The original size of the octagon was 13 inches inside measurement; but Mr. Paterson thought that, safely and with advantage, it might be extended to 14 inches. This gave an immense breeding and storing surface, every frame containing upwards of six thousand cells, a larger surface than that contained in any frame which we have ever seen. The result has so far justified this extension as indicated above, for breeding on a large scale has unquestionably gone on, the bees with their queen evidently chiming in with the idea. An experienced bee-keeper at the Perth Show urged that with such a mass of comb. brood. evacently chiming in with the idea. An experienced bee-keeper at the Perth Show urged that with such a mass of comb, brood, and honey in each frame, removal to the heather would be impossible owing to the risk of a breakdown, but he overlooked the additional support which the oblique upper and under sides of the octagon afford, thus counteracting the supposed danger. But the experiment has not been tried.

In all the apiaries of the district super honey has been almost, I might say altogether, a failure. I took a few pounds from a rectangular plaster hive which was not allowed to swarm, and whose population consequently could be counted by myriads. Mr. Paterangular plaster hive which was not allowed to swarm, and whose population consequently could be counted by myriads. Mr. Paterson, however, who was nearer the heather, took from his new hive 16 lbs. in boxes and 5 lbs. from the combs, leaving a large supply for winter use. The other twelve hives were a complete blank. This is all that can be said for the present. But he anticipates another advantage. The bees are clustering lower down on the comb than he ever saw them, and he fully expects from the arrangement of the stores all round the swarm that there will be no need for the bees removing from comb to comb all the winter. no need for the bees removing from comb to comb all the winter through, thus saving serious risk, as every bee-master knows to his cost, the scarcity of supply necessitating the removal, and paralysis from cold frequently occurring in consequence. Next spring I will return to the subject.—ALROFI.

A MISTAKE.

A GENTLEMAN in Derbyshire writes to me as follows, relative to a lecture on "Modern Bee-keeping" delivered at Belper on November 4th:—"The lecturer stated you have recently changed your opinion as to the relative advantages of large straw akeps and wooden bar-frame boxes, and that you now recommend the and wooden par-frame boxes, and that you now recommend the latter. As this is so very different from the view expressed in your book I think there may perhaps have been a mistake made, and therefore I shall be glad if you will kindly inform me if the fact is as the lecturer stated. I am sorry to trouble you, but my excuse must be the importance which you attach to using the best

I am obliged for the information conveyed in the above extract, and beg leave to say here that the lecturer has made a mistake, and beg scarce or say mean count in a made a mistake, for my views on the relative advantages of straw hives remain unchanged and unmodified. I am increasing the number of my stocks, all made of straw, because I prefer them. Some seven years ago I received a letter from a working man in the south of England, who ventured to predict that I should be converted and tallowed in the hearthman sweeten before I die. believe in the bar-frame system before I die.

About two months ago a nobleman who was then travelling through England called to see me and asked many questions about bees, one of which was in these words:—"After all that has been said in favour of bar-frame hives do you still prefer those you have used and recommended?" "Yes, most certainly" was the answer given to this question.

A. PETTIGREW.

OUR LETTER BOX.

COVERING HIVES (J. G.),—Your wood covers—2 feet square and 1 toot high, shaped like a dog kennel—will protect your hives from rain, and a good packing of soft dry hay between the hives and their covers during the cold weather of winter and spring would help your bees much and add to their countors; but such small houses made of thin materials should be painted white in summer to reflect the burning rays of the sun. We have known combs melt and fall, and the bees smothered in such houses under a hot sun. Any time next month or in January remove your hives into the place where they have to stand. All should be removed at once, and every vestige of their present stands obliterated.

BEE-KEEPING IN NEW ZEALAND (M.) .- M. M. would like to know some BRE-REPING IN NEW ZEALAND (M).—"M" would like to know some of the chief difficulties she would have to contend with in keeping bees in Auckland, New Zealand. She would feel obliged for a few suggestions on their management out there. They are said to swarm at all times, or at any time of the year, while owing to the weather never being cold cough to keep them at home, they do not care to store. Is this really the case? We shall be obliged if any of our readers, acquainted with bee-keeping in that part of New Zealand will favour us and our fair correspondent with some reliable information on the points inquired about.

REMARKS.

- 19th.—Damp morning, slight rain, fine after 10 A.M. with intervals of bright sunshine; very fine sunset; cloudy evening.

 30th.—Slight snow at 8.30 'a.M., very heavy 9 to noon, slight at intervals after 1 P.M., some bright sun about 0.15 P.M.; ground white with snow all day.
- snow all day.

 \$1st.—Foggy morning, thickly falling snow from 11 A.M. to 0.30 P.M.;

 \$.50 P.M. snow commenced again.

 \$2nd.—Further fall of about a tenth of an inch of snow during the night, making a total of nearly 4 inches; duil cold morning, slight snow shower 9 A.M.; very dark in the forencom; bright from noon till 3 P.M.; frosty starlight evening.

 \$2nd.—Very cold morning, snow still on ground; slight fog, but sky nearly free from cloud; fog gradually increased, and was dense from 8 till 9.50 P.M.

 \$4th.—Dull cold day, partial thaw; slight rain in evening.

 \$5th.—Little snow still on the ground, fine with bright sunshine; drissle in evening.

- in evening.

 By cold week, with an unusual amount of snow for the season.— A very cold G. J. SYMONS.

From observations taken near London during forty-three years, the average day temperature of the week is 47.8°; and its night temperature 35.4°.

EXHIBITING ROSES.

N common, doubtless, with many of your readers I have received and carefully perused the new number of Mr. William Paul's "Rose Annual," containing, among other articles, an interesting letter from "Wyld SAVAGE" on Rose exhibiting, its expenses, &c.

Since the writer says that the number referred to is a Rose Annual, not a newspaper, it must be at least twelve months before an answer can be given in it. I must ask him to accept an apology, if he thinks one necessary, for any comment upon his letter, which I only write because I

fear some readers may be deterred from Rose exhibiting by the expenses stated to be necessary, or may indulge in ill-founded expectations as to their probable chances of immediate success, and may be induced at least to wait a year before beginning their preparations, or may be disap-

pointed where they looked for success. First, the writer starts with two assumptions—that the exhibitor is to begin his career in nine months from this time, and then that he is at once to make a bold dash for metropolitan and other central shows, and this with purchased Roses. Now unless Roses behave very differently in his soil than they do in mine, any attempt to cut a good box from bought Roses the first year will only end in failure. I find that from however good a grower they may come, and however carefully they may be tended, the check by removal is so great that it is hopeless to expect their summer blooms to be up to the exhibition pitch. By plentiful watering during dry weather they will make fairly good wood in summer and will, perhaps, flower well in autumn, but their earlier blooms will have no chance with those cut off established stocks, especially from those which have never been disturbed since they were first budded. Again, however large and good the collection may be, the chance of success at the central exhibitions will be small until the grower has learnt (what only experience will teach him)

how best to cut, mount, show, and carry the blooms.

Acknowledging the writer's experience as at least more varied than my own, I should still wish to give my own ideas of the expense and process necessary to secure moderate success at first, and to give a reasonable hope of the highest honours in the future.

Assuming, as "WYLD SAVAGE" suggests, twelve hundred Roses in sixty varieties as the number which the amateur is prepared to grow, let him purchase (in 1879, say) three of each for budding from, at a price for dwarfs of £7, and twelve hundred stocks (this allows two hundred for blanks). These latter will, if standards, at 5s. per hundred, the price I pay, come to £3. If dwarfs, Briars or Manettis, they will, I presume, be somewhat less. For my own part I buy and prefer dwarfs, but bud half-standards simply because, doing my own propagating, I find knees and back not so supple as they were.

his price and say £20 for manure for twelve hundred Roses. I, however, have plenty of manure made on my own premises, and pay £2 or £3 for soot.

Now in no case, as I said before, would the rising exhibitor have any reasonable hope of success in 1880, and in 1881 he would have the same number of Roses as if he had bought his twelve hundred in 1879, and the account would stand as follows: -Roses, £7; stocks, £3; manure 1880, £4; manure 1881, £20; total, £34, as against "WYLD SAVAGE'S" £60 or £90, as the case may be. To this we must add what he omits—£8 for boxes, tubes, and other appliances.

The exhibitor's travelling expenses would not be much the first two or three years. He would confine himself, if he is wise, to local shows; and may be sure of this, that till he can hold his own and more at these it is no good trying a higher flight. I myself cannot spare time and money for the great shows, taking up three days in preparation, showing, and returning; but can find half a dozen local shows within an hour or so by rail. After a few years he may try his luck at the great shows, but not successfully, I think, with twelve hundred Roses.

Again, the writer mentions the necessary disbudding as a great drawback to the pleasure of exhibiting, especially where there are more than one in the family to be gratified, and he certainly does disbud with a vengeance. "The plant is only allowed to grow three or four blooms." Is this necessary or advisable? I trow not. I have had, as I said, some thirty years of Rose-growing, and have tried all kinds of experiments, and the conclusion I have come to, that every shoot we grow, if they are not allowed to be too crowded at first, may bear a flower without detriment to plants or blooms. The removal of all the buds from any shoot simply starts the wood buds below, and drives no strength into the other blooms. You secure an earlier midsummer shoot and that is all.

I may say that I have no such difficulty at home as "WYLD SAVAGE" has. This vanishes where the helpmeet was brought up as girl almost next door to a veteran exhibitor, and, early knowing what a Rose should be, thinks no exhibition variety worth looking at if not up to exhibition

standard. Besides, I pay expenses and she takes the prizes.
In another point "WYLD SAVAGE'S" practice differs from that of other writers on the subject. He "thinks it a great mistake to apply manure at the time of planting." This, on the other hand, is recommended by all the authors whom I have studied, and their recommendation is confirmed by my own experience. Soils differ, and what Roses may suit me in a strong clay may not suit him.—Duckwing.

PEARS VERSUS PEACHES.

I AGREE with the excellent remarks of "Essex" (p. 401) on this head; to only one point therein do I make an exception, and that is his considering Marie Louise to be so unimportant as to exclude it from his list. My opinion Manure varies in price according to locality. I could buy good farmyard manure for half the price "WYLD should experience a serious loss. Indeed out of a number SAVAGE" pays, but to make the comparison fair I will take of varieties grown my employer says Marie Louise is the NO. 1627.-VOL. LXII., OLD SERIES.

NO. 975.-VOL. XXXVII., NEW SERIES.

best; and certainly fine ripe fruit of this Pear is as good as

any gentleman could desire on his table.

I have for some years had very fair crops of Marie Louise on a tree trained horizontally on a wall; it has borne well every season. This year the standards and pyramids have borne very poorly. The cordon mode named by your correspondent would be a capital plan for one to try to prove the varieties best suited to a place, though a good well-developed fan or horizontally trained tree on a wall would, I think, be the most profitable if one only could be sure of what to plant.

Last winter I suggested a Pear election, but the idea was not

carried out. It is to be hoped, however, that this subject will have the full attention its merits deserve, as certainly the Pear is the very best of our hardy fruits. This year with me Pears have been about an average crop, better than Apples. Jargonelles produced a good crop and of fair quality, though this Pear does not keep long. Williams' Bon Chrètien was fair, but this Pear is very uncertain in quality, though for appearance it may be all that can be desired. After this we had in use Comte de Lamy and Louise Bonne of Jersey; now we are using Marie Louise. Beurré Clairgeau has had a fair crop this season—a fine-looking fruit, but not of superior quality. Beurré d'Aremberg always bears freely; though it is only second-rate for dessert, it is very good for stewing.

Good Pears on walls would prove far more profitable than Peaches or Nectarines. However, making the change, as your correspondent suggests, is not always convenient. Last year we cut down a number of well-developed standard Pears of useless kinds. This winter I would, if permission were given, remove a number from the walls, and occupy the space with

better varieties .-- R. M. A., Cheshire.

GLADIOLI.

JUST at this season, when the Gladioli are ceasing to bloom, the question arises about the policy of lifting them and storing them for the winter. 1 recently sent for Mr. D'Ombrain's shilling book on the Gladioli, and I find that he never once mentions the matter; he seems to take it for granted. Therefore, as this book was written a few years ago I presume that it is a modern idea. Mr. Douglas, I think, strongly advises cultivators to leave them in the ground through the winter; but large growers in the midland counties as strongly advise me to lift them. My friend Mr. Boscawen, the great horticulturist in Cornwall, however, advises me to leave them in the beds. He says he has adopted this course for years, and has found it answer extremely well. Now it may be a question of climate and deep planting, and one for which it is impossible to give a formal rule; but still a few opinions on this point which are formed from the results of experience would be acceptable perhaps to more than one.

The Gladiolus is such an exceedingly handsome flower, there are so many hundreds of fine varietics, so many shades of colour are being introduced, and, what is best of all, the French varieties are so cheap, that anything that throws light upon the culture of these charming flowers must be acceptable.-WYLD

SAVAGE.

AGAINST HARD PRUNING .- No. 2.

HAVING in a previous paper alluded more particularly to the Apple, I shall now suppose the question put to me, "Well, what about Pears? Surely you would not recommend us to throw away our pet pyramids and cordons?" This part of the subject is not to be disposed of in so simple a manner as that which concerns Apples, but must be divided and subdivided according to size of fruit anitability of divided and subdivided. according to size of fruit, suitability of climate and soil, habit of particular varieties as to growth, fertility, &c. There are some varieties quite as hardy as Apples, and which seldom fail as standards to produce a crop. I recommend such to be planted with and treated exactly like standard Apples—i.e., left to grow in a natural manner. I should be badly off at the present moment but for such a tree of the good old Comte de Lamy, which in this ungenial season has borne four or five bushels of fruit, not large certainly, but of excellent quality. This variety never fails as a standard, is almost independent of the seasons as to quality, and, unlike many of the more showy varieties, lasts a month or five weeks in condition. is another of fair quality which bears well as an unpruned standard, and ripens with me about Christmas time, when it is often extremely useful, as a quantity of one sort may then be required for a festive gathering. In addition to these I

recommend for the same treatment Jargonelle, which always bears best on the young wood, Williams' Bon Chretien and Joséphine de Malines, although this Pear never has a good flavour with me, it being bitter, and I have it in almost every conceivable position. Everybody else says it is a good Pear, and I must bow to the majority. At any rate it is a good bearer. Also add Louise Bonne of Jersey. a sure bearer; Marie Louise, Fondante d'Automne, and Suffolk Thorn, a delicious little Pear. Beurré d'Amanlis and Beurré Hardy are larger, and if the situation is not too much exposed to rough winds they may be depended on. There are probably other varieties suitable for this purpose which do not occur to me at this moment, the principal qualifications for which are hardiness, productiveness, fair quality, and medium-sized fruit,

Next there are some Pears which, owing to their large size, require shelter from rough winds, but are sufficiently hardy to ripen both wood and fruit in an ordinary season without the assistance of a wall. I think it is generally admitted that a Pear which will come to perfection without a wall is best grown without it as far as quality is concerned, but here, of course, latitudes, altitudes, and seasons have to be taken into account. In some seasons such varieties as Doyenné du Comice, Thompson's, and Beurré Superfin are excellent from pyramids, but this year with me Thompson's has failed to fruit, and the other two are only half grown. As these, then, are three of the best Pears in existence we should provide for a failure in the open garden by having a tree or two of each against a wall. Finally, there are some Pears which absolutely require a wall and are worthy of it; such are Bergamotte Espere, Easter Beurré, Gansel's Bergamot, Glou Morceau, Pitmaston

Duchess, and Van Mons Leon Leclerc.

Now as to the manner of pruning. The wall being a necessity to certain varieties, it is, of course, useless to plant them there and let them grow wild. Some portion of the wall must be exposed to the sun's rays, and all the growth must be exposed, or we defeat the very purpose for which the wall was built. Pruning, therefore, to a great extent is unavoidable; but let no one think pruning is an unmixed good, no plant can be cut back to the same bounds year after year without suffering from it in the course of time. I have met with tres which have been kept closely spurred-in for a number of years till they produced little else but fruit spurs, and the fruit was becoming less and less in size every year; notably of Van Mons Leon Leclerc on a south wall, which altogether refused to extend at the extremities of the branches. It was a model of training, but I wanted fruit. Some of the spurs which happened to have wood buds at the end were nailed back to the wall instead of being trimmed off in the usual way, and the result was almost like magic-the hidebound stems burst their bark, the fruit was larger even the first scason, and by following up the system of encouraging extenseason not excepted. I hold, then, that as pruning is only a necessary evil, it should not be carried to extremes even will wall trees. Train the main branches thinly, so as to get the full benefit of solar heat; do not pinch too hard in summer, rather remove some of the shoots altogether; encourage extension at the extremities, and if that fails do not hesitate to encourage extension for a time wherever you can get it, for without it fruit of the best quality cannot possibly be produced continuously.

With pyramids I fail altogether to see the necessity for close pruning. A tree a yard high with a dozen fruits on it is pretty enough, but I do not consider it is more beautiful than a larger one, and I am sure you cannot obtain so large a quantity of fruit from a given space of ground. Knight's Monarch makes a particularly handsome tree if merely kept thinned without shortening the growth. I could point to three trees of this variety, each about 12 feet high and nearly as much through, brought into a pendulous habit by the weight of fruit, which are pictures of symmetry, and in which a robin could scarcely hide itself in summer. Jargonelle also makes a handsome tree treated in this way, and it always bean the best fruit at the extremities of the shoots. Fondante d'Automne grows more upright, but it, too, is very handsome if merely kept thinned. Josephine de Malines has a habit of its own, its width being greater than its height. To sum up this part of the subject, I may say that I am convinced that where the soil is sufficiently holding to produce growth which is long and strong it is a folly to persist in growing pigmies, whether it be by using dwarfing stocks or by constant manipulation of the growth. In a very few years I expect Quince

and Paradise stocks to follow the road which I am now happy to see standard Briar stocks are taking, and we shall have discovered afresh the astounding fact that a very good Pear can actually be grown on a Pear tree-a fact tolerably well known to our great grandmothers, but one which we modern scientific horticulturists have either lost sight of or wilfully ignore.-WILLIAM TAYLOR.

CLASSIFICATION OF ROSES.

THE article of the Secretary of the National Rose Society ("D., Deal"), on this subject calls for, and will doubtless receive, careful attention. The subject is one requiring very full discussion, and the present is exactly the time for beginning it. I will therefore state shortly my own ideas on the subject, following the lines he has laid down, in the hope that

others also will express their opinions.

I am sorry to seem to differ in any way from so high an authority, but the National Rose Society Committee is very tolerant of variety. To begin with, I think the existing two classes are more generally called "Any kind" and Teas and Noisettes than Hybrid Perpetuals and Teas and Noisettes. Baron Gonella is a good solid Rose, even more likely to offer than Souvenir de la Malmaison as an "Any kind." In two Rose associations I have seen the exclusive Hybrid Perpetual class given up. I protest individually against turning Noisettes out of the Teaboxes. As it is, it is hard enough to stage twelve perfect blooms in this class; and if we are to lose Cheshunt Hybrid and the Noisettes are the lose of the Noisettes. and the Noisettes very few indeed, except the largest growers and the Noisettes very few indeed, except the largest growers and those who have glass, will be able to attempt this. I submit that Cheshunt Hybrid in the early bud stage is a great addition to a stand of Teas, however fatal it may be when it commenced fading—crimson colour is so much wanted; but here, of course, tastes may be hopelessly at variance. A difficulty now has most certainly arisen, and a question will have to be decided. I confess to myself inclining towards accepting the new Hybrid Tea class that has arisen, and I would relegate to it all Roses with unquestionable Teas or Noise would relegate to it all Roses with unquestionable Tea or Noisette blood—e.g., even La France, Capitaine Christy, and Boule de Niege.

I do not see my way to letting in any of these amongst the Tes and Noisette class for exhibition, and the "Any kind" class is already too large and too strong for some of these, so that I almost incline to suggesting a class of their own. Mr. Bennett has made such a grand addition, though I have not yet seen any of his Roses in full force, that Hybrid Teas may be expected soon to demand recognition. Only a few, perhaps, will be able to hold their own like La France in the "Any kind," and yet I should equally deprecate with "D., Deal," letting them all into the Tea and Noisette class. The poor Noisettes! I hope somebody else will feel for them as I do. Letting alone Maréchal Niel, who can take care of himself anywhere, and Céline Forestier, who is not very dependable, only think of Caroline Kuster, the excellent solid new lemon yellow, and Lamarque, how fine when not coarse—and lovely Narcissa, with its special fragrance; and that good clear solid yellow, again, Triomphe de Rennes, all extinguished for the future! I protest, on the behalf at least of these, most emphatically, and would rather add to this class than diminish its numbers, though I admit the great difficulty arising now of dealing with these new Hybrid Teas. It is very unlikely they would be seen much in "Any kind" boxes, and some have certainly too much Hybrid Perpetual blood to be admitted amongst Teas and Noisettes; hence the problem by no means too soon propounded by the far-seeing Secretary of the National Rose Society.-A. C.

SHEFFIELD BOTANICAL GARDENS.

In your issue for November 6th, page 363, is a well-written albeit brief notice of these fine old gardens, which I was very glad to see. I visited these gardens eight or nine years ago as a perfect stranger, and was charmed with them; I also found the geniality and courtesy of the able Director, Mr. Ewing, just as your representative has written. Ouvirandra had leaves 16 inches long and nearly 4 inches broad, and "lots on em" too. Platycerium biforme or P. stemmaria (I forget which) was very attractive growing in a flower pot reversed and suspended from the roof of a warm plant house. Especially delighted was I with the Ouvirandra and other rare aquatic plants, and the rare plants of particular rather than general interest which find a proper refuge in the classical old botanical gardens like Magnum Bonum Potato. I am given to understand that it

those of Sheffield, Oxford, Liverpool and others. I am sure you are right in your concluding sentiments with respect to Mr. Ewing, whom I have always found most generous in his aid and encouragement of younger men. As an instance of this please allow me to say that I recently asked Mr. Ewing for some rare plants; one was especially rare and valuable in the trade as well as in a botanical sense. This one Mr. Ewing could not spare from his own garden, but he took the first opportunity of procuring it for me from a friend. It now graces our collection, and I never look at its progress without feelings of gratitude towards its generous donor. The story is a true one, and the moral is not obscure.—A YOUNG CURATOR.

CONSERVATORIES IN WINTER.

WELCOME as flowers always are, they are especially so in the bareness and gloom of winter. It is now that the conservatory is estimated at its true value, and when well cared for is very attractive to all. How to turn it to best account becomes, therefore, a question of importance. The frequent application for a heating apparatus simply for the exclusion of frost, apart from the question of economy, shows the prevalence of much ignorance about the necessary temperature of such a house in winter. Simply to exclude frost is not enough; we require a temperature sufficiently high to render the air tolerably free from moisture, cold moisture-laden air being fatal to foliage and flowers. A minimum temperature of 50° will suffice to effect all we wish, for in it plants will grow slowly, the foliage keep a fresh green healthy hue, flowers continue to expand and remain in beauty a long time.

Common Russian Violets planted in beds and borders among tall-growing plants continue flowering from September to March. Mignonette, sown in early spring and grown in pots, comes in with the Violets, which are transplanted in clumps from their summer quarters in the open air. Palms continue growing; not only the hardy Chamserops Fortunei, C. excelsa, and C. humilis; but Phœnix dactylifera and the very beautiful Phœnix reclinata, Latania borbonica, Areca sapida, Sabal Blackburniana, Calyptrogyne Ghiesbrechtiana, and others, all imparting relief to the brilliant zonal Pelargoniums that in such a temperature continue in flower throughout the

Tree Carnations should also have a prominent place; they do not give "a blaze of bloom" like the Pelargoniums, but are nevertheless highly valued for the beautiful flowers they continue to unfold for so long a time. Raised by cuttings taken as early in the year as possible, and grown on through the summer, no plant can be more agreeable than the freshness and vigorous appearance of good specimens when brought into their winter quarters. Miss Joliffe, King of the Belgians, Marchioness of Westminster, Princess Christian, Queen of the Belgians, Rosy Morn, La Belle, Scarlet Defiance, and White Nun, are all good.

Chinese Primulas, Cinerarias, Cyclamen persicum, Libonia floribunda, Heterocentrum roseum, Camellias, Oranges, Erica hyemalis, E. gracilis and E. gracilis vernalis, Epacrises, and such Fuchsias as Splendens, serratifolia multiflora, Dominisma, Beauty of Trowbridge, and Mrs. Burroughs, all combine to afford an ample variety of winter flowers. There should also be a fair proportion of such berry-bearing plants as Ardisia crenulata, Solanum Capsicastrum, Aucubas, and Iris fœtidissima. Upon the value of Chrysanthemums during early winter I need not dwell; but attention should be called to the value of the Scabious for the conservatory in winter. I have some three dozen bushy plants just coming into flower raised from seed sown last March, which are exceedingly ornamental, and embrace shades of colour ranging from rich velvety black, through crimsons and pinks to pure white.

If possible avoid all staging in the interior of a conservatory, and also much formal grouping of plants for effect. Beds and borders with a carpeting of Lycopods, Musk, and Violets are always most liked. A few good well-grown plants are infi-nitely preferable to a crowd of rubbish, and by the exercise of a little ingenuity and taste the smallest building may be rendered attractive without formality.—EDW. LUCKHURST.

MAGNUM BONUM POTATO.

In the number for October 23rd your correspondent "An OLD GROWER" states that it would be well if it could be stated to whom the credit is due of having raised the original was raised by a Mr. James Clarke. I obtain this information from Messrs. Carter's farm seed catalogue for 1877, wherein they state that they have obtained their supplies from Mr. Clarke, who, I have since ascertained, resides in the neighbourhood of Christchurch, Hants.—FACT.

AURICULA CULTURE.

WE of the older generation of florists are receiving some rude shocks to our nerves in the matter of Auricula growing. We never had woolly aphis in the days of our youth, and damp was the chief enemy we had to contend with; but other matters are also noticeable. One of the most successful growers in the north, Mr. Woodhead of Shobden Head, Halifax, grows all his plants now in highly glazed non-porous pots. This is a violation of all rules that have hitherto guided growers of plants, who have been specially warned against the use of such unscientific articles; and yet I am told by Mr. Rudd of Bradford that the whole collection is in the most perfect health—a testimony I can readily believe from some of the plants which I have seen, which were admirably grown. Mr. Woodhead tells me that the saving of time in watering is very great, for of course they do not require watering so often.

My friend Mr. Llewelyn, so well known as an enthusiastic horticulturist, and who has been so successful as an Auricula grower, has broken in upon the old established order of things, and in the cultivation of seedlings and offsets has adopted a plan which I think will be hailed with satisfaction by those who have a large number of plants; and having mentioned it to me, and being desirous that others should have the benefits of his practice, he has very kindly drawn out the following paper for the Journal, and I have great pleasure in forwarding it, hoping that it will commend itself to others as it has done

to me.-D., Deal.

NOVEMBEE would seem to be a dreary season to talk of spring flowers, and though it is the dull time for Auriculas yet in our spare moments we are never tired of thinking of them; and a proposal in our little fraternity of florists, while we are revising schedules and prize lists for 1880, of a special prize for seedlings which our energetic Secretary Mr. Douglas of Loxford is working at, leads me to think a few notes on the culture of Auriculas may prove of use to some who grow seedlings, and perhaps to others who have little time to devote to or space for the supervision of any beyond a few of the best.

Much has been written on the culture of the Auricula in pots, and I have little to add excepting my testimony to the necessity for cleanliness, dry surroundings in the damp season, and above all thorough drainage to prevent the pots becoming waterlogged. I wished to explain more particularly my plan of growing duplicates and seedlings for which there is no room in the Auricula house. For such varieties as Col. Taylor (Leigh), Anna (Trail), Prince of Greens (Headly), among the greenedged; Alexander Meiklejohn (Kay), George Lightbody (Headly). Lancashire Hero (Lancashire), among the greys; Smiling Beauty (Heap), Glory (Taylor), Catharina (Summerscales), among the whites; Lord of Lorne (Campbell): C. J. Perry (Turner), Pizarro (Campbell), in the self-edged class a dozen which rank in the front, though followed very closely by many others well worth any cultivator's attention-pot culture is certainly advisable, with every care that can be bestowed. There are numbers of varieties to be found in every catalogue, well worthy of a place in a collection from their brilliance and beauty, but not worth growing for the exhibition table on account of some fault that is inexcusable in a florist's Here let me observe that the price quoted in the catalogues is governed far more by the ease with which the particular variety is divided and increased than by its merit. example, Summerscales' Catharina is a true and beautifully correct white-edged variety, only small, yet it is cheaper than many of inferior worth; and so will it ever be, those commanding the highest prices which most sparingly produce their offsets, and which are at the same time the most sought after.

Well, then, if the good varieties are few, yet many of inferior merit are worth growing. I wish to show how they may be grown with little trouble yet satisfactory results, and an experience of three or four years emboldens me to recommend the plan. First, at top-dressing time, which commences with the last days of January or the 1st of February, we find on our plants many offsets by which the stock is to be increased. Some are already rooted, and with these there is no difficulty, for they can at once be treated as established plants. Others,

however, have no roots, and here I cut off the little offset with a sharp knife, or break it off if it can be done easily, healing every wounded surface with finely powdered charcoal. These unrooted offsets are then inserted 2 or 3 inches apart in a small unheated propagating frame, in soil composed of silver sand and cocoa fibre. By the first week of May the whole of these, with scarcely an exception, will be well rooted and ready for their summer quarters. I then place them in frames, each of which is 9 feet long by 4 feet wide, with a gentle slope from back to front. In the bottom is a thorough drainage of broken crocks, then roughly cut turf, with about one-third of decayed manure and a small quantity of silver sand well incorporated. In this the plants are placed 4 inches apart, so that I find my frames hold about 140 plants each. The light of the frame is about 9 inches above the soil and is easily removeable in fine weather, and I have found small offices have grown more rapidly under this system of culture than they would had they been brought on in pots. Once planted they are easily managed, for while the glass light protects them from storms it may be removed to admit a genial rain, and shading is easily applied in scorching sunshine. The saving of labour is so great that hundreds of plants may be grown where dozens were grown before.

The Auricula, and indeed most of the Primula family, may be moved when in full flower without injury; and I have dug up plants in bloom, potted them, and taken them direct from the protected border to an exhibition, and they have shwn scarcely any signs of flagging then or afterwards, and the flowers have remained fresh for days after.—J. T. D. LLEWELYN,

Ynisygerwn, Neath.

POND'S SEEDLING PLUM.

I FIND this a most useful kitchen Plum, forming an excellent succession to the Victoria, and in some respects proving superior to that good old variety, than which it is considerably larger quite as prolific, but scarcely so good in flavour. This season, however, seemed to suit Pond's Seedling, as we never before had it so good, and although not good enough for dessert purposes generally, a few dishes we ventured to use of it at a large tenantry dinner were apparently appreciated. The cook prefers this variety to any when in a green state for compôtes, tata, &cc., on account of the richness of the syrup it helps to form. We commenced sending them in when as large as good-sized Walnuts, and continued doing so at intervals till those leftcommenced colouring. These thinnings, too, materially benefit the remaining crops, in fact the operation is quite necessary if good fruit is wanted. The ripe fruit is very fine for either jam or terts.

We only grow standard trees, and they very seldom fail to carry heavy crops. They are of very vigorous habit, but should be well pruned until a fine head is formed. When this is the case, which with us was about the third year after planting, the long strong shoots were not shortened, only judiciously thinned. At the same time, ours being a strong soil, we thought it advisable to root-prune, though only very lightly. On a light soil this operation, however, is scarcely necessary. The first season after this treatment we had a fair crop, the next and following seasons the crops were remarkably heavy. Nothing can be more ornamental than these trees when the fruit is ripe, the long and slightly arching branches throughout being evenly laden with fine bright red fruit. Very little pruning is now required beyond shortening back any very straggling shoots and thinning out where likely to be too crowded.—W. IGGULDEN.

DODECATHEONS (AMERICAN COWSLIPS).

Considering that some of the members of this genus have been introduced into this country from the western hemisphere over a century it is rather remarkable, if we do not take all things into consideration, that they are not more frequently met with; but if we remember that they are placed in the category of hardy plants there is no place for surprise, since many of the most beautiful floral gems have been despised simply because they did not require a glass erection and a certain degree of temperature, as many of the more favoured pets of the general plant-grower do. The time is not far distant when the value of many hardy plants will be fully recognised. But coming to the subject of this short paper, it is no difficult matter to say that the American Cowslips are among the handsomest of hardy flowers. They belong to the Primlaceæ, and in growing them it is most beneficial to associate

them with such plants as Primulas, Soldanellas, and Cyclamens. Where any one of these genera will flourish they are equally happy. If a bed is set apart after due preparation to Primulas you may depend upon the Dodecatheons flourishing as well. It is necessary that the position selected should be a moist and shady one. We have seen Primulas planted in sunny positions, and unless constant and copious supplies of water are given them during a dry season they are literally baked. They succeed remarkably well on the rockery, planting them in shady places, readily establishing themselves, and flowering very freely. Some of our growers recommend for their successful culture light peaty soil. With that treatment, however, we do not agree, knowing well that although they thrive in light peat soil, at the same time the result of experience is greatly in favour of employing light loamy soil, leaf soil, and sharp sand, which is also an excellent soil for most of the Primulas. Planted on the rockery in a small portion of that soil they will succeed well and the result will be satisfactory.

The typical forms of Dodecatheon are all natives of North America; some of the varietal forms of D. Meadia may have originated in our gardens, or have been introduced as natural varieties, since, like almost all the genera of Primulaceæ, they are easily worked upon either by artificial or insect agency. They are all perennials, easily increased by division of the rootstock or from seed, although the seed if sown in spring is frequently slow in germinating-in fact we have had it germinate after being in the pots a twelvemonth. The seed should be sown as soon as ripe, but if purchased from a seedsman it is as well not to discard it until all probability of its germination is past. They produce erect racemose spikes of pendulous Cyclamen-like flowers during the early summer months, with the segments of the corolla sharply reflexed. The generic name assigned to these plants by Linneus is very absurd, as it literally means "twelve divinities," and like a multitude of other names the similarity or associations of the subjects in question with those represented only rests in a very remote region of the imagination. Below are enumerated the species and varieties with which we are acquainted.

Dodecatheon integrifolium.—Widely distributed over North America, varying to some extent; it grows from 9 to 12 inches high, producing numerous spikes of bright crimson flowers which last a considerable time in beauty. This is as handsome and durable as any of them.

D. Jeffreyanum.—This is a more recent introduction than the last; it varies in height from 1 to 2 feet, usually growing about 18 inches high, producing strong scapes of bright rosy purple flowers, which are also rather larger than those of the last.

D. Meadia.—This is the most common of the series, and is frequently known as the "Shooting Star of the West." It is very widely distributed throughout North America, and there is a large amount of variation, which has originated the establishment of many varietal forms. The typical form produces scapes about a foot high, bearing several flowers of a lilac or rosy red colour. It is a very valuable species, and will thrive well in ordinary borders if a select position is given to it and a little attention. For growing in pots it is valuable, and the cultivator is well rewarded. Other varieties of this species worth growing are album, which is similar in all respects to the type, but has white flowers. Elegans is a charming variety; the flower scapes are freely produced, bearing several large bright rosy lilac flowers. This is also a vigorous grower. Carneum, with very delicate blush flowers, produced in very large umbels. Giganteum, a tall-growing variety 18 inches high: the umbels large, bearing dark rose-coloured flowers.—T.

DIGGING AMONGST FRUIT TREES.

FOR several seasons I have never forked or dug the ground near the Raspberries, only spreading the dung on the surface, and the crops have invariably been excellent. Had I depended on the trees to which manure is turned in annually for our supply of Apples and Pears this season I should have been quite without fruit, but on the trees which have not been disturbed for years the crops were abundant. This is not a chance result, for I have observed the same fact during previous years.

I should be pleased to hear if any of your readers have observed the same result. My opinion is that annual digging amongst fruit trees destroys the surface roots and causes the lower roots to take a deeper hold of the soil until they penetrate into an unfavourable subsoil, then follows unfruitfulness.

It may have been observed that trees with their roots deep in the soil are very often as green in the foliage as any other, but although the blossoms are abundant only a few set fruits are produced, and these either fall off while young or become cracked and woody when old. This is the result of my experience, and the very opposite is the case with trees which have not been disturbed for years. I have lifted and replanted nearly every fruit tree and bush in our kitchen garden this autumn. The roots of all have been mulched over with dung. This will be done every winter when necessary, but the manure will not be dug in amongst the roots.—A KITCHEN GARDENER.

SCHIZOSTYLIS COCCINEA.

This useful autumn and winter-flowering plant is of recent introduction, having been first received in this country in 1864 from Kaffraria, a territory of South Africa. With me it is quite hardy, but if unprotected it is so late in flowering that its beauty is in a great measure destroyed by the frosts. To see its beautiful crimson flowers in the best condition they must expand under glass. The plant requires a compost of good sandy loam, peat, and leaf soil in equal quantities and thorough drainage; the pots should be plunged in sand in a cold pit through the summer. Any person who wishes to have a grand display in beds may do so by growing plants on during spring and early summer in pots and plant them out in early autumn, protecting them from frost when necessary.—IRID.

CHRYSANTHEMUM AND FRUIT SHOWS. KINGSTON-ON-THAMES.

More than usual interest attached to this Show, in consequence of the competition for the twenty-five guinea challenge cup provided by the President and Vice-Presidents of the Society, under the following conditions, for twenty-four incurved and the same number of Japanese blooms—"The winner to hold the vase till the next Exhibition, when it shall be returned to the Society. Should the same exhibitor win the vase twice (not necessarily consecutively), it shall become his property, but should it be won by three different exhibitors in the first three years, then the competition in the fourth year shall be confined to the three winners." All subscribers of one guinea are allowed to compete, and in the first contest Mr. Harding, gardener to T. D. Galpin, Esq., Bristol House, Putney Heath, was the winner; Mr. Moorman, gardener to Miss Christy, Coombe Bank, Kingston-on-Thames, being second; and Mr. McPherson, gardener to S. Page, Eaq., St. Leonard's Lodge, Surbiton, third. Mr. Harding was very strong in the incurved section, but rather weak in Japanese; Mr. Moorman staging the best stand of Japanese blooms in the Show, but his incurved flowers were more than a week past their best. Mr. McPherson's blooms were more regular, but in neither section strong enough to attain a higher position. The class was a difficult one to judge, but the verdict was undoubtedly correct, there being about half a dozen points between each collection. Mr. Harding's Japanese stand contained Fulgore, very pale; Fair Maid of Guernsey, Criterion, Elaine, and Sultan, all fine; Peter the Great, Jane Salter, and Chang (good), Comtesse de Beauregarde (fine), Sarnia, Nuit d'Hiver, Ethel, Diamond, Tendresse, and Gloire de Toulouse, all small; Hero of Magdala, Hiver Fleur (chaste), Fulton, brilliant yellow; Magnum Bonum, and Dr. Masters (small). The incurved varieties were Queen of England, John Salter (fine), gardin des Plantes, Empress of India, Lady Hardinge, White Venus, Princess of Wales, and Mrs. G. Rundle, all good; Guernsey Nugget, Nil Despe

In the class for twenty-four blooms of distinct incurved varieties there were six exhibitors, the display being very good. Mr. Tunnington, gardener to C. McIver, Esq., Calderstones, Liverpool, obtained the premier award with an excellent collection of well-formed even blooms, including a selection of the best varieties in cultivation. The following were especially noticeable for their freshness and symmetry:—Sir Stafford Carey, Mrs. G. Rundle, Mrs. Dixon, Princess Beatrice, Golden Empress of India, Barbara, Eve. and Hero of Stoke Newington. Mr. J. Clarke, The Gardens, Roehampton Lodge, secured the next position of honour with blooms but slightly inferior to Mr. Tunnington's in freshness and form; Golden Empress of India, Mr. Corbay, Prince of Wales, and Venus being extremely well represented. Mr. Harding, who was placed third in this class, staged a good collection but containing several weak points. Mr. E. Berry exhibited the best collection of twelve incurved blooms, his varieties being well chosen, the flowers distinguished by their substance and neatness in outline;

Bronze Jardin des Plantes, Alfred Salter, and Nil Desperandum were superb. A. Duncan, Esq., Chislehurst, followed with smaller and not quite such even blooms, and Mr. J. Masters received the third prize for a collection very close in point of merit to the last third prize for a collection very close in point of merit to the last mentioned. The four other exhibitors in this class staged fair blooms generally, but each collection contained sufficient weak blooms to prevent them from obtaining honorary positions. Mr. J. Beard, gardener to J. Shand, Esq., Fullbrook, Old Malden; Mr. J. Lyne, Wimbledon; and Mr. W. Clark, gardener to A. Nagle, Esq., Kingston, secured the chief prizes in the class for six incurved blooms. curved blooms.

The display of Japanese varieties in the three classes devoted to them was highly attractive, the distinct and bright colours and singular forms of these varieties considerably relieving the monotonous symmetry in the incurved varieties. Mr. Tunnington was awarded the chief prize in the class for twenty-four blooms of distinct varieties. The blooms were rather small but remarkable for freshness and brightness of colour, and as one of the Judges remarked, Mr. Tunnington would have proved a formidable antagonist had he entered for the challenge cup. Some of the finest blooms in this collection were The Cossack, Tokio, Wizard, Nuit d'Hiver, The Daimio, Golden Dragon, Leopard, Mr. Charles Hubert, and the neat little white Laciniatum. Mr. Richards, Surbiton Hill, was a good second, but his varieties were Michards, Surbiton Hill, was a good second, out his varieties were not so distinct nor the blooms so fresh as in Mr. Tunnington's collection. Mr. W. Rowman, gardener to J. J. Wilks, Esq., Oatlands Park, obtained the third prize with fair blooms but somewhat deficient in substance, although the selection of varieties was commendable. Mesers. Hinnell, King, and Lyne carried off the prizes for twelve Japanese blooms, all showing examples of the most popular ways also in most. The collections of the most popular varieties very close in merit. The collections of six Japanese blooms were not distinguished by any special degree of excellence generally, although Messrs. Beard and Masters exhibited several good flowers.

In the one class devoted to reflexed varieties the exhibits were In the one class devoted to reflexed varieties the exhibits were not in first-rate condition generally, although Christine, Beauté du Nord, and Garibaldi were well shown by Mr. J. Rowman, who obtained the first prize. Messrs. Hinnell and Richards were awarded the remaining prizes for blooms of only medium quality. Mr. Moorman staged the best collection of twelve blooms, Anemone varieties, Gluck and Queen Margaret being very neat in form. Messrs. Rowman and Berry followed with blooms of average merit. For twelve bunches of Pompon varieties Mr. J. Lyne obtained the premier award with fair specimens, the other exhibits in that class being rather poor.

exhibits in that class being rather poor.

Plants.—In a structure so large as the Drill Hall, in which the Exhibition was held, plants in considerable numbers are essential for furnishing the building and rendering it attractive. Some admirable miscellaneous groups, each occupying space not exceeding 100 square feet, were arranged in a semicircular manner at the end of the hall. The prizes in these groups went in the following order:—First, Mr. Beard, gardener to J. Shand, Esq., Fulbrook, Old Malden; second, Mr. Attrill, gardener to C. J. Freake, Esq., Park Grove, Kingston; and third to Mr. Hinnell, gardener to F. A. Davis, Esq., the President of the Society. Both in the quality of the plants and their arrangement the collections were excellent, Mr. Beard's group finding favour presumably as containing more flowering plants than the others, notably a free sprinkling of Poinsettias.

Four prizes were offered for collections of Chrysanthemums in pots, space not exceeding 50 feet. The competition was extremely close. The premier award fell to Mr. Moorman for a close and close. The premier award fell to Mr. Moorman for a close and gay arrangement, the blooms being fine, the varieties numerous, and colours well mixed. The plants were grown in a natural manner on single stems, and many of them appeared unusually dwarf for this form of culture. Mr. Luff, gardener to W. Subonadiere, Esq., Delta House, Worcester Park, was an excellent second, the foliage being better than in the premier collection; Mr. Richards, Surbiton Hill, third, with dwarf and standard-trained plants; and Mr. King, gardener to R. Few, Esq., Wolsey Grange, Esher, fourth with vigorously grown plants bearing fine blooms.

fine blooms.

In the class for six dwarf-trained specimens Mr. King was far in advance of other competitors, three of the plants being upwards of 6 feet in diameter, and not 3 feet high in the centre. These three specimens probably contained five hundred blooms. Mr. Richards; Mr. Child, gardener to J. Gray, Esq., Claygate, Surrey; and Mr. Beard had the remaining prizes in the class. For standards Mr. Plowman and Mr. Beard had the chief prizes, and the first-named exhibitor brought a pair of concentrics—that is, standards with grafted beehive-like heads, the rings of colour being yellow, white, yellow, pink, and a terminal apex of white. Mr. Lyne, The Gardens, Belvidere House, Wimbledon, was the principal exhibitor of Pompons.

Table plants and Ferns for the dinner-table were arranged down the centres of the tables devoted to the cut blooms of Chrysanthenums, and afforded agreeable relief to the formal masses of colours. For table plants the prizes went to Mr. J. Lyne, Mr. King, Mr. Richards, and Mr. Beard, all of whom exhibited neat specimens of Dracænas, Crotons, and Palms. The Ferns were generally rather too dwarf and bushy for the purpose of table decoration, but otherwise good. Messrs. Hill, Beard, and Buckland were awarded the prizes in the order named. Primulas were also fairly well exhibited by Mr. Clarke, gardener to A. Nagle, Esq., Kingston; Mr. Watson, gardener to Captain Cundy, Norbury House, Surbiton; and Mr. Attrill, who were awarded the prizes in the and control of the prizes in the angle parader careful. in the order named.

Of fruit there was a moderately good display. Mr. Bichardson secured the premier prize for six dishes with very large bunches of black and white Grapes, two dishes of Apples, and two of Pears; Mr. Luff following with a very neat collection, the Grapes being smaller; and Mr. Beard. Mr. King won the first position for four dishes of Apples, two dessert and two culinary, with Cox's Orange Pippin, King of the Pippins, Blenheim Pippin, and Beauty of Kent, fine; and for four dishes of Pears Mr. Attrill was first with Beurré Diel, Hacon's Incomparable, Brown Beurré, and Duchesse d'Angoulème. Messrs. T. Jackson & Son, Kingston, exhibited Vines in pots bearing fruit, also excellent Black Alicante Grapes, good table plants, Ferns, &c., which contributed an agreable feature to the Show.

Altogether the Exhibition was a very good one, and was well managed under the able direction of Mr. Jackson, jun., the efficient Secretary. It was held on the 27th and 28th ult., having been postponed from the 20th, but in the opinion of many exhibitors the Show would have been better if it had been held on the original date, when both plants and blooms had not lost their

freshness.

BIRMINGHAM.

The nineteenth annual Exhibition of the Birmingham and Midland Counties Chrysanthemum, Fruit, and Flower Society was held on the 26th and 27th ult. in the Town Hall, Birmingham, In accordance with the usual excellent custom the Mayor granted the free use of the noble Hall for the purpose, and it was filled to the free use of the noble Hall for the purpose, and it was filled to repletion with the various exhibits. The display of dwarf and bush-trained large-flowering, and Pompon Chrysanthemums was unquestionably the finest of the year. No standard plants were shown such as those exhibited so well at the Westminster Aquarium and Walton, and the cut blooms were by no means equal in numbers or quality to those that have been staged in London and its vicinity wet a few of the stands were were good. Primples its vicinity, yet a few of the stands were very good. Primulas were a prominent feature of the Show, no less than thirteen classes being provided for them, all of which were well filled, while in some the competition was great. Many of the plants were remarkably fine, far excelling those usually seen at metropolitan exhibitions. Fruit was admirably exhibited, Grapes, Apples, and Pears being both numerous and excellent; and bouquets were above the common order of merit. Indeed Birmingham may justly be credited with producing one of the very best

exhibitions of the present autumn.

In addition to the first prize in the class for nine plants of In addition to the first prize in the class for nine plants of Chrysanthemums, a silver cup was provided as the premier prize of the Show. This was nobly won by Mr. Dyer, gardener to T. W. Webley, Esq. All the specimens in this collection were good, three of them being truly grand; they were the beautiful trio Mrs. G. Rundle, Mr. George Glenny, and Mrs. Dixon. These fine examples of culture were from 6 to 7 feet in diameter, somewhat in the form of inverted squeers and shout 3 feet high in the what in the form of inverted saucers, and about 3 feet high in the centre; they were not so thinly tied out as many large plants are, nor were the blooms small; on the contrary, the flowers were good, and there were six hundred of them on the three plants. The other varieties in the group were Prince of Wales, Baron Benst, Chevalier Domage, Lord Derby, John Salter, and Lady Hardings—a splendid group. The second prize went to Mr. Denning, gardener to J. Jaffray, Esq., for much smaller yet neat although overtied specimens, all the plants being of the same size and as regular as if cast in a mould. The plants in the third-prize group of Mr. Padbury, gardener to R. P. Yates, Esq., were trained in a more natural and upright manner, good in foliage, and some of them carrying blooms of great merit; but for one or two failing plants in the back row this collection would have had the second position, and was left very reluctantly by the Judges. In the minor classes the plants generally were very good, notably the single specimes of Mr. Dyer, and the three plants of Mr. Stacey, gardener to F. Ostier, Esq., which obtained the premier prize in their class.

Pompons, although affording signs of having been advanced in what in the form of inverted saucers, and about 3 feet high in the

Pompons, although affording signs of having been advanced in heat, were much the finest we have seen this year. Mr. Dyer exhibited massive but rather overtied plants upwards of 5 feet in diameter, and Mr. Stacey grand round naturally trained bushes, good in foliage and flowers, and obtained the chief prizes in the good in longe and nowers, and obtained the chief prize in the principal classes. Mr. Doughty, Mr. Jinks, and other exhibitors also staged well and successfully. The best cut blooms were exhibited by Mr. J. W. Silver; they were not large, but fresh and well finished. Messrs. Warrender, Shingler, and Hampton also

had very creditable stands.

Primulas were remarkable for their numbers and excellence, the size of the plants and quality of the flowers being such as are seldom seen. Hundreds of grand plants were staged, forming an exhibition, and an attractive and meritorious one, in themselves. The principal exhibitors were Mr. Caldicott and Mr. Tompkins, who secured many prizes. Messrs. Pache, Pope & Son, Jinks, and

Denning were also successful in several classes. Mr. Stacey exhibited admirably grown Solanums, as also did Messrs. Pope & Son a compact and fine-berried variety named Empress.

Table plants were staged in excellent condition by Messrs.

Stacey, Herne, and Jinks, who secured the prizes in the order
named. Mignonette was well shown by Messrs. Denning and
Hooper, Poinsettias by Mr. Blake, Cyclamens by Messrs. Pope
and Son, and Encharises by Mr. Palmer; very fine specimen stove
and greenhouse plants by Messrs. Jinks, Jones, and Dyer, who
were placed in the order named; and Mr. Vertegans exhibited excellent Poinsettias presentable dwarf and fine American Tuberce cellent Poinsettias, remarkably dwarf and fine American Tuberoses, Calanthes, and Ferns. The prize bouquets of Messrs. Fulton and Sons and Pope & Son in the nurserymen's class, and Messrs. Jones, Scarf, and Jinks in the amateurs', were exceptionally good, the prizes being awarded in the order of their names.

prizes being awarded in the order of their names.
Fruit was a prominent feature of the Show. For a collection of six dishes Mr. Bannister, gardener to H. St. Vincent Ames, Esq., Westbury-on-Trym. Bristol, was placed first with superior Lady Downe's and Muscat Grapes, an excellent Melon, with fine Pears, good Apples, and a dish of Peaches, Mr. J. W. Silver and Mr. Willis securing the remaining prizes. For four dishes Mr. Denning was first with black and white Grapes, Pears, and Apples, all good. The class for three hunches of black Grapes brought. good. The class for three bunches of black Grapes brought out ten competitors. Mr. Dyer won the premier position with Black ten competitors. Mr. Dyer won the premier position with Black Alicante, the bunches about 2 lbs. in weight, being of good shape, full, regular, and well finished. The other prizetakers were Mr. Stacey, Mr. Willis, Mr. Rawbone, and Mr. Hooper, gardener to Sir Josiah Mason, who all staged admirable produce. White Grapes were not so good, the prizes going to Messrs. Bannister. Crawford, and Sayer. Pines call for no comment, but Apples and Pears were excellent. In these classes Mr. Gardiner, gardener to E. P. Shirley, Esq., Ettington Park, Stratford-on-Avon, a well-known excellent cultivator, contributed admirably and successfully. His first-prize collection of twelve dishes, six dessert and six culmary, comprised fine dishes of Warner's King, very large; Northern Greening, Yorkshire Greening, Golden Noble, Round Winter Nonesuch, New Hawthornden, Wyken Pippin, Ribston Pippin, Adams' Pearmain, Fearns' Pippin, Kissington Pearmain, and Mannington's Pearmain. Mr. Bannister was second in this class. For six dishes Mr. Elcock was first with fine fruit, Dumeclass. For six dishes Mr. Elcock was first with fine fruit, Dumelow's Seedling being quite red; Mr. Gardiner second, and Mr. Willis third. For twelve dishes of Pears Mr. Bannister was first with a collection of great merit, including Marie Louise, Maréchal de Cour, Beurré Clairgeau, Hacon's Incomparable, fine; Gansel's Bergamot, excellent; Knight's Monarch, Beurré Sterckmans, Easter Beurré, Duchesse d'Angoulême, and Seckle. Mr. Gardiner was second with fine fruit, and Mr. Willis third. For six dishes Mr. Gardiner was in the foremost place with fine fruit of Easter Reneré Reneré Diel Louise Bonne of Jersev. Dovenné du Comice. For six dishes Mr. Elcock was first with fine fruit, Dume-Beurré, Beurré Diel, Louise Bonne of Jersey, Doyenné du Comice, Madame Treyve, and Beurré Superfin. Mr. Elcock was first for a single dish of kitchen Apples with grand examples of Dumelow's Seedling, first for dessert Apples with Radstock Beauty, and first for Pears with Pitmaston Duchess—beautiful fruit, which must either have been grown under glass or in a remarkably fine climate outdoors. Cucumbers were good from Mr. Crawford, and Mushrooms from Mr. Willis.

Considering that the prizes throughout the schedule were not by any means high much credit is due to the exhibitors for producing so fine a Show, and to the Secretary, Mr. Redfern, Messrs.

Latham, Spinks, and others, for managing it so well; yet the
system of judging and affixing the prize cards is not the best, and
did not enable us to obtain the names of all the prizetakers and

the addresses of but few of them.

CHELMSFORD.

The autumn Exhibition of the Chelmsford and Essex Horticultural Society was held on the 26th ult. Amongst nurserymen Messrs. Saltmarsh & Son were the only representatives in the first seven classes, while amongst amateurs some of the classes were only contested by one exhibitor, many others by only two, and very few indeed by more than three. To Mr. Joseph Tunbridge, gardener to Mr. W. Bott, The Priors, Broomfield, the merit is due of staging the best plants in the Show; his Mrs. G. Rundle, due of staging the best plants in the Show; his Mrs. G. Kundle, Jardin des Plantes, Lady Slade, and others amongst large-flowering varieties measured quite 4 feet in diameter, beautifully trained, and well flowered; while his Pompons were scarcely less, and were also beautifully finished. Mr. John Burrell, gardener to W. Duffield, Esq., Broomfield, also staged good plants, well grown and trained, and came in for a good share of the prizes. Mr. W. Smale, gardener to Robert Woodhouse, Esq., Writtle, was, we believe, the gardener to Robert Woodhouse, Esq., Writtle, was, we believe, the only exhibitor who adhered to the single stem style of growing, the result being that his plants were neither so large nor so bushy, but his flowers were the finest exhibited. Mr. E. Warner, gardener to P. Marriage, Esq., Broomfield; and Mr. J. Lay, gardener to F. Christy, Esq., Broomfield Road, were also amongst the prizetakers. The plants of Messrs. Saltmarsh were not large, but very well grown. Mr. F. Kemp, gardener to C. H. Gray, Esq., Chelmsford, and Mr. W. Smale had capital collections of miscellaneous cut flowers, the prizes going in the order named. The best cut blooms exhibited were Favourite. Bronze Iradin des Plantes. Hercules. exhibited were Favourite, Bronze Jardin des Plantes, Hercules,

George Glenny, Novelty, White Globe, Pink Perfection, Prince of Wales, Queen of England, Mrs. Haliburton, Venus, Lady Hardinge, and Ossian; while Pompons were Golden Cedo Nulli, Pink Cedo Nulli, Cedo Nulli, Bob, Dragon, White Perfection, and Mauve Cedo Nulli, Cedo Nulli, Bob, Dragon, White Perfection, and Maure Queen. Black Grapes were fairly represented by Mr. S. Augur, gardener to W. W. Perry, Esq., Springfield, with three bunches or Alicante; and Mr. Davis, gardener to F. Chancellor, Esq., with Black Hamburgh. Mr. E. Hammond, Broomfield; Mr. C. Pilley, Broomfield; Mr. C. Carville, gardener to the Lord Bishop of St. Albans; Mr. H. White, Bell Cottage, Chelmsford; Mr. J. Fulcher, gardener to J. G. Conder, Esq., Chelmsford; Mr. A. J. Clark, gardener to the Hon. A. Petre; and Mr. J. Clark, Writtle. were prominent amongst the prizetakers in fruits; and excellent baskets of vegetables were exhibited by Messrs. J. Burrell, F. Kemp, E. Hammond, and Josh. Tunbridge. A fine collection of about fifty varieties of Potatoes were staged by Mr. T. H. Hill, gardener to A. W. Ruggles Brise, Esq., Witham, and was deservedly awarded an extra prize. The same award was also made to Mr. J. Clark for a superior collection of Apples and Pears, about forty varieties. The Committee were present to carry out the arrangements, assisted by Mr. P. Edwards, the hardworking Secretary. Secretary.

NOTES AND GLEANINGS.

WE are pleased to learn that the Committee of the GAR-DENERS' ROYAL BENEVOLENT INSTITUTION have caused to be purchased in the names of the Trustees the sum of £300 3 per cent. consols, thus making the total amount now standing in their names £12,000, from which an annual income will be derived of £860.

THE annual meeting of the NATIONAL ROSE SOCIETY will be held by permission in the rooms of the Horticultural Club, Arundel Street, Strand, on Thursday next, December 11th, at 3 P.M. The annual dinner will take place the same evening at 6.30.

- WE are informed that the peculiar sweet fleshy flowers of Bassia Latifolia, which are eaten by the natives of some parts of India, are now being imported into this country by Messrs. Christy & Co., Fenchurch Street, London, as food for poultry, pigs, &c. This tree is a member of the tropical order Sapotaceæ, and is called by the natives of India Mahwah or Mahva. The corollas when mature become fieshy, and contain a large proportion of sugar; they have a slightly bitter, but by no means disagreeable flavour, and doubtlessly contain a large amount of fat-forming constituents. In some parts of India a powerfully intoxicating spirit is obtained from these flowers, of which it is said as much as an English pint can be purchased for the equivalent of a halfpenny.

ONE of the most effective displays of CHRYSANTHE MUMS that has ever come under our notice is arranged in a large Peach house in the gardens of Mrs. Torr, Garbrand Hall, Ewell. The house is a lofty span-roof about 100 feet in length, with a path down the centre. On both sides of the path Mr. Child has improvised espalier-like fences of stakes and string to which the plants are secured, forming hedges of bloom about 6 feet high. At intervals arches are carried overhead across the path, and covered with white, buff, pink, and yellow Chrysanthemums, the whole arrangement forming a magnificent promenade. The plants are on single stems and are admirably grown, many blooms being very fine, and yet are in great profusion. Also the entire length of the house is a close row of Mrs. G. Rundle, the plants being dwarf and densely covered with flowers producing a charming effect. About 350 plants are employed in the arrangement, and anything more beautiful than the effect produced is not easy to imagine.

A SIMILAR arrangement is carried out in the conservatory at EWELL CASTLE, which Mr. Scutt invariably has so gay, orderly, and enjoyable. In one of the houses in the kitchen garden—one of a block of very useful plant structures erected by Messrs. Weeks & Co.—is a charming display of Calanthes, the spikes of C. vestita lutea being especially numerous and fine. They are displayed, too, to great advantage by being associated with small plants of Dracenas, Poinsettias, Ferns, &c., and the structure is extremely attractional content of the structure is extremely attractional content. tive. The plants generally in this garden are in admirable condition, being especially healthy and clean, scarcely a decayed leaf being visible, nor an insect to be seen throughout the establishment.

THE appearance again of the flower spikes of the beautiful SCHIZOSTYLIS COCCINEA remind us of their value as well as extreme beauty at this season of the year. If it is grown in a rather sheltered border of rich soil, planted in goodsized clumps through the summer, taken up and potted in 48-pots before the frost affects it, and placed in a frame or greenhouse, the bright scarlet flowers which are copiously produced will not only be found ornamental but very useful.

MR. WARREN of Hurstbourne Park Gardens, desires us to state that he did not purchase his "seed" of CARTER'S MAGNUM BONUM POTATO, which he referred to disapprovingly on page 312, from Messrs. Carter & Co.; but "obtained it from a respectable seedsman, with whom he has dealt largely for some years, and has never had any reason to doubt his strict fidelity in all business transactions." Mr. Warren desires that this statement be made, in order "that readers of the Journal may not be prejudicially influenced in their purchases of Magnum Bonum." In reference to this question Messrs. Carter state that they have searched the orders of the seedsman referred to in their books without tracing any purchase of Magnum Bonums from them, and they further assert that their selected stock is from the original, purchased by them in 1877 from the raiser.

THERE are several species and varieties of COLCHICUMS now grown in our gardens, but none perhaps are so beautiful as the charming C. speciosum, which comes to us from the Caucasus. The flowers are similar in colour to those of C. byzantium. rich rose, but very much larger. while the foliage is also ornamental. Any of the forms are well worthy the attention of the hardy bulb grower.

— A CORRESPONDENT informs us that the recently introduced PRIMULA CASHMIRIANA, which is only a variety of P. denticulata, has flowered well this autumn, several flowers having yet to expand. The umbels are of a good size and very handsome. P. rosea, also a recent introduction, grows very freely in the neighbourhood of London. and is sure to become a general favourite on account of the richly coloured flowers.

— IN Dr. King's report of the ROYAL BOTANICAL GARDENS, CALCUTTA, for 1878-79 are some interesting remarks on the cultivation of the Bamboo as a paper-yielding material. It appears that Mr. Routledge's original scheme of annually cutting down all the shoots on each clump does not prove successful, and that the only feasible plan is the removal of a few shoots each year. It is stated that Ipecacuanha, Rhea, the Baobab, and the Pará rubber (Hevea braziliensis) do not thrive in the Calcutta district, and the cultivation of the latter is to be discontinued. The Ceará rubber (Manihot Glaziovii) is, however, likely to prove a valuable crop.

— MR. C. CORDERY, late of Canford Manor, succeeds Mr. Nicol as gardener to Sir John Kelk, Tedsworth, Marlborough. Mr. MARKS, late gardener to H.R.H. Prince Christian, Cumberland Lodge, has been appointed gardener to E. E. Kay, Esq., Q.C., Thorpe Abbott, Scole. Mr. W. SMITH, late of Barnfield, Southampton, succeeds Mr. Scott as gardener to the Bishop of Winchester, Farnham Castle; and Mr. D. SNELLING, Longton Hall, succeeds Mr. Stalker as gardener to the Earl of Lucan, Laleham, Chertsey.

— "THE COLONIES AND INDIA" of the 22nd ult. contained a useful supplement—viz., a list of works treating on tropical products and economic botany. It is the joint work of Mr. G. J. Symons, F.R.S., and Mr. P. L. Simmonds, and gives the names, authors, and dates of a very large number of authoritative works. It will no doubt prove of considerable utility to botanists and gentlemen engaged in tropical agriculture.

MR. WILLIAM PAUL'S ROSE ANNUAL FOR 1879-80.

THIS Annual contains four handsome coloured plates which appear to me to be excellent specimens of the chromo-lithographic art. I take in several gardening periodicals, but I do not remember to have been so pleased with any plates as these, The artist's name is not given, but the lithographer is F. De Tollenaere.

The best plate according to my judgment is that of the very dark novelty Jules Chrêtien. This is simply wonderful. The foliage is intensely dark, almost the colour of a Camellia, but with a sheen of silver and a fluffy carpet as it were super-added. The flower reminds me of a very fine specimen of Xavier Olibo, but with a better centre than we usually see in that Rose, unless we pay a visit to Heavitree, to that salutary mount where even thin Roses lose their weakness, and change their consumptive tendencies to the most robust health. The other plates are three offerings of Mr. William Paul to the Rose gardens of England. The first in the book is a noble salmon-tinted pink

Bose called Pride of Waltham. If the artist has not flattered this Rose we have here a grand globular light-coloured Rose which combines the attraction of Mdlle. Eugénie Verdier with somewhat of the form of Clemence Racux. The next is Masterpiece, and a masterpiece it is both of Rose form and of the artist's skill. We have here almost perfection of form, each petal being so beautifully made as to remind me of a Camellia. It is a seedling from Beauty of Waltham, but the colour may not be so bright as we are accustomed to see in the parent, but there is a shading or glow of silver which lines the edge of the petals which is very charming. The third Rose honoured with a plate is a new miniature Moss variety called Little Gem, or Crimson Moss de Meaux. It is more mossy than the old Rose de Meaux, but in other respects is much the same.

With regard to the literature Mr. Paul gives us a very interesting summary of the weather of this extraordinary season with a short resume of the Rose shows of the year; also he has a fling at myself and other writers who have ventured to express their opinions on the synonyms in the nomenclature of Roses. But whilst naming the varieties which have been pronounced to be identical he contents himself merely with some general remarks as to the ease with which he himself has attached a correct name to each if fair specimens were brought to him. I must say that when reading this article I was in hopes that so great an authority as Mr. W. Paul would have gone gravely and at some length into the matter; that he would have told us how Ferdinand de Lesseps differed from Exposition de Brie, and how Maurice Bernardin might always be distinguished from both his stable companions. Perhaps Mr. Paul in a future edition will enter into this question and furnish us with some reliable facts on which to act. There is no doubt that a nurseryman who grows Roses by hundreds of thousands has far better opportunities of doing this than an amateur who buries a few hundreds in his churchyard. Mr. Paul's opinion is of course more valuable than any mere amateur's word; still, till he does what I have suggested I must venture to maintain my own opinion that the three Roses referred to are identical.

It is exceedingly gratifying to observe how well the English nurserymen are maintaining their ground as compared with their French brethren in the matter of introducing novelties. Here we have the two—may I venture to call them "apostolic firms."—sending out from four to five grand novelties each year. From Royal Windsor, or rather Slough, also come two or three fine additions to our roseries; and now from the stony soil of Wilts, from the farm of Stapleford, we are told that nine novelties are ready to be sent out to all who will pay half a guinea each for them, while as a grand Christmas box it is whispered that a yellow Perpetual is to be had; so that in Rose-growing as well as in all other horticultural art old England is holding her own.—WYLD SAVAGE.

OUTDOOR PEACHES IN THE NORTH OF ENGLAND.

YOUR correspondent "ESSEX" will be interested to know that here, 240 miles north of London, Peaches on open walls have only twice failed to ripen during the last twenty years. Last year upwards of twelve dozen were gathered from one tree alone, and nearly all the others carried a fair average The fruit produced by these trees is of superior size crop. and quality. This year the trees on a south wall in the kitchen garden have been seriously injured by the long-continued east winds which prevailed in the spring; while two trees on another south wall, which is well sheltered on the east side by the house, have not only escaped injury but have each produced a good crop, which, however, has failed to ripen. The only protection the trees receive is a double herring net from the time the blossom begins to open till the fruit is set.—T. RICHARD-SON, The Gardens, Brettanby Manor, Darlington.

FRUIT TREES IN PERFORATED POTS.

HAVING been requested to furnish further particulars of this mode of growing fruit trees as described on page 380, we reply by submitting the annexed representation of a tree as grown in Mr. Rivers' nurseries at Sawbridgeworth. The engraving is from a photograph, and shows clearly the great amount of support the trees receive when the pots are plunged in good soil. The roots which issue from the sides of the pots are cut off annually when the leaves of the trees commence changing in the autumn, and the pots are replunged in the border, to which

fresh soil and manure have been applied. Than the Peach | trees grown on this system at Sawbridgeworth none could be

more thoroughly satisfactory. They had produced large crops | it for next year's crop. The plan is applicable to Pears, Plums, of superior fruit, and had produced fruitful wood and matured | and Cherries, which can, if desired, be plunged in the open

air during the summer; and good crops of Grapes could no doubt be produced by the same mode of culture.

THE HAILSTORM RELIEF FUND, 1879. REPORT OF THE COMMITTEE.

THE aggregate amount of damage to glass and crops by the disastrous hailstorm which broke over the districts of Richmond, Twickenham, Ealing. Kingston, Surbiton, Teddington, Brentford, Isleworth. Kew, Hanwell, &c., early on the morning of Sunday, August 3rd, 1879, was estimated at £4000; and although the Committee could not hope to raise that sum, they succeeded in obtaining enough to give substantial relief to many in the form of assistance towards replacing their glass.

The applications for relief from the fund were eighty-one in

The applications for relief from the fund were eighty-one in number, and the total of the statements of damages amounted to over £4000. Awards of money were made to sixty-two persons according to the extent of their losses and their needs. The parishes affected by the storm were arranged into four groups. An Investigation Committee was appointed to each in order to assess the damages incurred by applicants, and the work was very carefully and thoroughly done. The awards made were based on the recommendations of the Investigation Committee, who were authorised to ascertain all needful particulars, so that relief should be given only where deemed right and proper to do so.

The total subscriptions amounted to £1013 15s. 7d., and out of this £937 14s. 3d. was distributed in relief. The time necessary to raise the fund the Committee has administered took much longer than was at first anticipated, and it was necessary to employ a somewhat elaborate machinery both for collecting and administering the same; thus time and money were consumed somewhat disproportionately to the aggregate result.

The Committee feel that they are enabled to close their labours with satisfaction to themselves, and in the hope they have satisfied the subscribers to the fund. They have spared no labour nor pains to do the fullest justice to both subscribers and applicants. The Committee notice with pleasure, as in the case of the Hailstorm Relief Fund of 1876, that not a few of the subscribers and most active members of the Committee were themselves sufferers to a considerable extent. Their cooperation is therefore all the more deserving of commendation.

In conclusion the Committee heartily thank the subscribers of all classes who placed in their hands the means whereby they were able to mitigate much of the distress of some of their suffering brethren; the clergy and ministers of all denominations for their valuable and practical sympathy; the Investigation Committees for much self-denying labour, and all who in any way assisted to make the fund answer the purpose it was intended to serve.—HENRY F. LIMPUS, M.A., Chairman; W. PENNYFEATHER, Treasurer; RICHARD DEAN and EDWARD KING, Secretaries.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Forcing Department.—The season has been very unfavourable to plants employed for this purpose, and they require more time to start than in a season when the growths are earlier matured. To have Asparagus, Seakale, and Rhubarb fit for use at Christmas and the new year the roots should be placed in their forcing quarters at once. Asparagus should have a bottom heat of 70° to 75°, and an atmospheric temperature of 50° to 55°. The plants should be lifted as carefully as possible, for the less the roots are damaged the stronger will be the growth, as the produce is almost solely dependant for support on the rootlets that proceed from them. Light rich soil should be employed for covering the bed 2 inches thick. About 3 inches of spent tan or sifted leaf soil should be placed over the crowns after the plants have been put in, which will admit of the easy penetration of the heads and blanch them sufficiently. Seakale is easily accommodated in a Mushroom house, planting it in light rich soil. The better the plants are nourished the finer will be the heads produced, and bottom heat will also assist their growth considerably. It may be forced in a frame over a fermenting bed, the linings being frequently renewed so as to maintain a temperature of 55° to 60°. Rhubarb is finest and is produced more rapidly where bottom heat is provided, a fermenting bed with a temperature of 70° to 75° answering the purpose well. The great value of fermenting materials consists in their inducing speedy root-action. Rhubarb and Seakale, however, are readily forced in a Mushroom house. French Beans should be sown every fortnight or three weeks to maintain the succession unbroken. Chicory roots are readily forced, and the growth is blanched in a darkened Mushroom house. The Chicory

should have the tops cut off not nearer than an inch to the crown, and the roots planted in light rich soil. The Mushroom house must be heated and kept at a steady temperature of 60°, it being useless attempting to force Seakale, Rhubarb, and Chicory without heat, and many failures with Mushrooms occur through the uncertain and variable temperature of an unheated structure. If there is likely to be a scarcity of salads young plants that in the ordinary course would not come in until spring may be lifted and planted in light rich soil in the Mushroom house and they will make fresh blanched growth quickly. Dandelion roots may be lifted and treated similarly to Chicory, and when the growth is produced quickly and well blanched it is not despisable. Roots of Mintand Tarragon should be potted, or they may be planted in boxes about 4 inches in depth, 2 feet in length, and 1 foot wide, employing strong roots and light rich soil. They should be kept in a sheltered place and protected in severe weather, removing them into heat as required. Chervil lifted carefully and placed in boxes will be very useful if kept in a house with a moderate temperature. Potato sets should be placed in shallow boxes on the floor of a forcing house, laying them about 3 inches apart on leaf soil 2 inches in depth, and cover them about an inch deep with similar material; when the shoots are about 8 inches high raise the sets carefully, preserving the shoots and all the roots possible, and plant them in beds or pits previously prepared, placing them 15 inches apart, and covering them about 4 inches deep. The soil must be light and rich. Where space is available in Peach or Vine houses sets prepared as above may be placed in pots, one in a pot 9 inches in diameter, or three in a pot 12 inches in diameter, by which means early dishes may be obtained. Carrots and Radishes in the early stages of growth require good ventilation, closing and covering the frames only as may be necessary to secure the safety of the plants. The surface soil between the

Vines.—Those who desire to cut fresh ripe Grapes before the end of May must commence forcing in earnest. The outside border should have protection from cold rains and snow, and if possible a covering of litter and leaves, two-thirds of the latter to one of the former, should be applied. Borders that were covered in early autumn with litter or bracken will not require to be covered with fermenting materials now. The house having been previously cleaned, start the Vines with a night temperature of 50°, and 5° more in mild weather, which must not, however, be exceeded until the buds commence swelling. Syringe occasionally in the morning and early afternoon; but if a bed of sweetened stable litter and leaves be formed on the floor of the house or inside border the necessity for syringing will not be great, and the vapour given off by the fermenting material will be conducive to a vigorous and regular break. Prior to starting, the inside border should have a thorough watering with water at about 90°. In mideason houses the Vines will ere this have been pruned, or as the foliage has ripened late it may in some instances yet require to be done. The houses where the Grapes have been partially cut, and which it is desirable to clear out entirely for painting and other repairs, as well as for pruning, the bunches may be cut with a good piece of wood attached and inserted in bottles of water, placing them in any dry room from which frost can be excluded. Late varieties, however, such as Lady Downe's, should not be cut until the new year, and there will then be no difficulty in keeping them in good condition till May.

Excepting Sternbergia lutea, which appears to defy all weathers, there is little to attract notice in the herbaceous borders. Christmas Roses are also valuable for winter and early spring, the flowers being greatly appreciated. Where handlights are available they should be at once placed over the plants, as the flowers come much larger and are better in colour when protected in this way. There is always great danger in digging herbaceous borders at this season unless the positions of all the plants and bulbs are clearly indicated by stout hard wooden pegs. In the case of bulbs and the commoner plants this is generally considered sufficient, although it adds much to the interest of plants to have them properly named. The borders being cleared of decayed flower stems and withered foliage, a good dressing of manure or leaf soil should be given to enrich the soil and act as a protection against frost. Pyrethrums, Delphiniums, and others subject to the ravages of slugs should have the soil removed from around the crowns, dusting with quicklime, and instead of replacing the soil place ashes about and over the crowns. Rats and mice also often make great havoc amongst bulbs. Ere winter sets in in real earnest plants of doubtful hardiness should have the necessary protection.

Bambusas, Pampas Grass, New Zealand Flax, Chamærops Fortunei, and similar plants winter quite safely protected in this way, whilst dwarfer plants may have about 8 inches thickness of ashes placed around and close up to the stems or crowns, and over the latter if the plants are deciduous. Tender shrubs, &c., grown against walls should have the borders mulched with short litter or partially decayed leaves, and in addition a double thickness of mats in front of such plants as Magnolias, Ceanothuses, &c., will be necessary in severe weather. Beds of dwarf Roses should be well covered with Tea-scented Roses should be covered over the roots similarly, Tea-scented Roses should be covered over the roots similarly, and some bracken or hay threaded amongst the branches. The standards also should have a good mulching of litter over the roots, as when those are well protected the stems are generally safe. Beds or borders of Belladonna Lilies should be protected by strewing some half-decayed leaves over the crowns, as when the clumps become strong the finest bulbs are forced to the surface. They require good drainage, a warm situation, and security against frost, the same remarks applying to Alströmerias. Gladioli corms should be lifted, laid in a shed safe from frost until they are thoroughly dried, and then stored away in a cool dry place frost of course being excluded. Dablia roots should be lifted if not already done, and laid root upwards to part with superfluous moisture, and when dried store them away in sand. Cannas, Marvel of Peru, Tuberous Begonias, Salvia patens, &c., may be treated similarly to the Dahlias. Examine the beds of spring-flowering plants, and if any are loosened press the soil firmly about them, and if a mulch be given between the plants as were bade of bulbs of about manual partially depend on the plants as were bade of bulbs of about manual partially depend and the source of the plants as were bade of bulbs of about manual partially depend the plants as were bade of bulbs of about manual partially depend the plants as were bade of bulbs of about manual partially depend the plants as were bade of bulbs of about manual partially depend the plants as were bade of bulbs of about manual partially depend the plants as were believed to be a superior of the plants as were about the plants as well as well as well as well as well as well as well as well a as over beds of bulbs of short manure, partially decayed leaf soil, or cocoa refuse, it will be beneficial as a protection against frost. PLANT HOUSES

-All winter-flowering plants, such as Euphorbia jacquinisflora, Eranthemums, Poinsettias, Centropogons, Thyrsacanthuses, Centradenias, Gesneras, &c., should be placed near glass. Hard-wooded plants being now for the most part at rest a thorough cleaning should be made as time and opportunity offers. Syringing is the most ready means of applying an insecticide, but not by any means the most effectual, as mealy bug and scale are so protected by their outer coat. A brush, a sponge, and a pointed piece of wood are necessary to destroy mealy bug effectually. All insecticides are more potent if applied warm; hot water (120° to 140°) will destroy as many insects as one-half the preparations sold, which very often owe more to the mode of application than any-The temperature in this structure may now fall to its winter minimum-viz., 55° in the morning in severe weather, 60° to 65° by day by artificial means, and 70° to 75° with sun heat. 65° by day by artificial means, and 70° to 75° with sun heat. Very little ventilation will be needed, but a little should be afforded in mild weather, not to lower the temperature but to admit of a change of atmosphere. Water only to maintain the foliage in good condition. Deciduous plants should be kept dry, watering only to prevent the wood shrivelling. Caladiums should not be kept dust dry, but have the soil a little moist, the temperature being about 60°. Gloxinias and Achimenes should also have the soil a little moist, or they shrivel and do not start so strongly, and the corms of Gloxinias often decay if they are kept dust dry.

Both will winter safely in 10° less than Caladiums require.

Greenhouse.—Cuttings should be taken of Chrysanthemums, stout short suckers of about 8 inches in length, taking them off with about an inch of root stem, and inserting them singly in 8-inch pots; turfy loam with a fourth of leaf soil, well-decayed manure, and a sixth of sand answers. Three cuttings may be inserted in a 4-inch pot; place the pots on ashes in a cold frame, shading from bright sun, protecting from frost, and after the cuttings begin to grow ventilate the frame freely. The single plants will answer for growing in 9-inch, and the trebles for 12-inch pots.

TRADE CATALOGUES RECEIVED.

TO CORRESPONDENTS.

* All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense. Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

BOOKS (Gilbert).—We do not know of any book of the kind you appear to quire. Designs suitable for various positions may be found in back numrequire. Designs at bers of the Journal.

BOOK ON OLIVE CULTURE (B. Brothers). A work entitled "Tropical

Agriculture," published by Spon & Co., Charing Cross, price 21s., contains the information required.

BOOKS ON ORCHIDS AND GREENHOUSE PLANTS (A. R. F.).—Williams' Orchid Grower's Manual," and "Stove and Greenhouse Plants" would suft you; also Appleby's "Orchid Manual," and the "Greenhouse for the Manual," The two latter may be obtained from this office post free for 22.7 dal. a." 10d. respectively.

ELEMENTARY BOTANICAL WORKS (Rev. J. J. D.).—For a beginner we should recommend Oliver's "Elementary Botany," Lindley's "School Botany," Smith's "Domestic Botany," and Balfour's "Manual of Botany; "to be followed by Professor Lindley's "Osgetable Kingdom," and Dr. Hogg's "Vegetable Kingdom," both standard works of an advanced character.

BULBILS ON BEGONIA STEMS (M. D.) .- The occurrence of bulbils on the stems of Begonias is a possiliarity that characterises many species, being most marked in B. Martiana, B. bulbifera, B. discolor, and B. diversifolia. These bubbls when placed in suitable soil, &c., quickly grow into plants—indeed that is a very ready way of propagating them.

ARONIA GRANDIFOLIA (W. C. E.).—We are not acquainted with "Aronia grandifolia." Probably the tree to which you refer is Cratægus Aronia, a native of the Levant, which bears large yellowish fruits.

Making Mushroom Bed (M.J.).—A mixture of short stable manure and leaves will answer admirably for the lower half of your Mushroom bed. We have had many fine beds of Mushrooms when the lower portion of 6 or 7 inches consisted of such a mixture surfaced with the same thickness of horse droppings, the whole of the material having been properly prepared, and containing just sufficient moisture to induce steady fermentation. other question will be answered next week.

GAS LIME (W. W. B.).—It is chiefly valuable as a preventive of insect pests. It should be applied in autumn or some time prior to planting the crops, digging it in; for which purpose 20 bushels per acre is a sufficient quantity. It is suitable for most vegetable crops, and after it has been some time exposed to atmospheric influence is converted into sulphate of lime or gypsum, and is valuable as a dressing to grass land, lawns, &c.

PRUNING CLEMATIS (De Bosco).—If the plants are against a wall or trellis merely cut them back to firm ripe wood, thinning out where too crowded. If in beds remove all the spray and leave only sufficient firm wood for furnishing flowering growths in the ensuing season. In the case of young plants cut well back to plump eyes and firm wood at the base of the plants.

CALANTHE FLOWERS FALLING (W. M. A.).—It is due to the plants being kept too moist at the roots, the atmosphere being also too moist and the temperature too low. Keep them drier and warmer and they will expand. The house also is too moist and close for Gesneras, and not light enough.

HOT WATER FROM BOILER (A Subscriber).—The water from the boller may be used for mixing with the cold to render it of the temperature required for watering with, but it is not so good as that obtained from a tank or eistern in the house. This is the best time to insert Chrysanthemum outtings, and the best way to treat them is given in "Work for the Week," which see. Water from a new cement cistern is not injurious to plants.

MULCHING NEWLY PLANTED ROSES WITH COW MANURE (Ama MULCHING NEWLY FLANTED ROBES WITH COW MANUE (Amazer, Co. Durkers).—The manure, which we presume contains a large portion of straw-instead of being too cold is the best of all manures for Roses, especially where the soil is light; but if there is very little straw in the manure it would not be advisable to apply it more than an inch or two in thickness as a mulch, which would to some extent exclude frost. The salts would be washed down by the rains and enrich the soil, and would greatly invigorate the plants.

down by the rains and enrich the soil, and would greatly invigorate the plants. PREPARING STIFF SOIL FOR ROSES (As laquirer).—If you have added manure liberally to the ground in the process of trenching nothing further will be required; if not, a good dressing should be given and well mixed with the soil, and if you could at the same time add some fresh turfy loam it would be an advantage. The burning of "gault" (clay mar!) will have improved the soil by making it more open and pervious to air and moisture. The surface soil may be kept from cracking in summer by mulching with what the surface soil may be kept from cracking in summer by mulching with

PROPAGATING VARIEGATED IVIES (A. H.).—The best mode of increase is by grafting on stocks of one of the free-growing green-leaved varieties, of which cuttings can be struck in an open border. The cuttings may be inserted in early autumn, and when rooted be potted, and if placed in a close warm frame in early spring and grafted with the choicer varieties good plants of the latter are much sooner obtained than by striking them from cuttings. A good time for layering shrubs is late September. Some Confers are increased by layers, but the usual plan is to raise them from cuttings inserted in sand and placed in close pits, and by seeds. PROPAGATING VARIEGATED IVIES (A. H.) .- The best mode of increase is

Dissolving Bones (W. F. F.).—The quickest mode with which we are acquainted is by the aid of sulphuric acid. The bones should be broken assmall as possible, put into a tub, and be frequently stirred in a mixture of sulphuric acid and water. The proportions are 12 cas. acid, 12 cas. water, and 16 cas. bones. Another, but a slower mode, is as follows:—Take a large watertight hogshead, and cover the bottom with about 6 inches deep of dry wateright hogshead, and cover the bottom with about a inches desport dry soil; on this put a layer of bones of the same depth, and cover them entirely with wood ashes; on these another layer of bones, then ashes, and so on till the hogshead is full. Leave it exposed to the rains all summer and winter till spring; then on removing the contents of the hogshead the bones will crumble to powder under a slight pressure, and form one of the most valuable manures ready for immediate use. For fruit trees requiring aid the manure would be very beneficial.

would be very beneficial.

AURICULA APHIS (W.).—This pest is most difficult to eradicate, and we should adopt strong measures promptly. We do not think it would seriously injure the plants to wash their roots with parafin water at a strength of a fluid ounce of parafin to a gallon of water, the oil to be mixed with the water as thoroughly as possible. We grow Auriculas, but fortunately they are clean; yet by way of experiment we have watered some of the plants with parafin water of the strength quoted, and no injury whatever has with parafin water of the strength quoted, and no injury whatever has essuited to them. We regret the pest has been sent to you, but with the aid of Gishurst and parafin and the perseverance with which you intend applying these and other insecticides that may suggest themselves, we trust the aphis and not you "will have to retire defeated." We shall be glad to have the results of the contest.

HEATING GREENHOUSE FROM KITCHEN BOILER (Lemon) .- Two rows of 8-inch pipes round the house would afford sufficient heat for maintaining a stove temperature. The boiler must be below the pipes, the flow being inserted at the top and the return pipe at the bottom. The propagating pit may be formed over the pipes in any part of the house most convenient. If it is not convenient to take the pipes across the doorway two rows of 4-inch pipes, a flow and return, along one end and the front of the house under the stages would suffice. In that case we should have the propagating pit as near the boller as possible. The flow pipe should have a gradual rise from the boller to the most distant point, where an air pipe should be fixed, the return pipe having a gradual descent to the boller. You might consult an intelligent ironmonger or gardener with advantage in a work of this nature. If you send \$\frac{1}{2}d\$, in stamps to the publisher and ask him to send No. 769 of the Journal, you will find an illustrated account of a vinery heated successfully from a boller in the kitchen the perusal of which might be of some service to you.

HEATING HOUSES (Horatio).—Hot-water piping will be necessary for heating the houses efficiently. We do not approve of the plan you suggest, as we have seen a similar system tried, and it proved a complete failure. Heated air always ascends, and by the mode referred to the house would be much too hot at the back and too cold in front. Either a saddle or tubular boiler will heat the houses satisfactorily. When boilers are set in brickwork there is a conservation of heat, but we know of portable beliers which give great satisfaction to those who employ them. Select the boiler which appears best adapted to the position. The system of glazing you mention will answer for the hothouse.

FAILURE OF ASPARAGUS (A Lady).—The low temperature and excessive wet of last summer is the cause of the newly-planted Asparagus decaying. Healthy plants planted in the same soil will doubtlessly succeed if next summer prove favourable.

CHRISTMAS ROSE (*Idem*).—The Christmas Rose is Helleborus niger. It is a native of Austria, introduced to this country some three hundred years ago. Spring is the proper time for transplanting them, but it may be done now by the exercise of a little extra care. The Lobelis plants taken from the beds and potted will come into flower in your greenhouse in spring.

the beds and potted will come into flower in your greenhouse in spring.

GRAPE VINES UNPRUITFUL (A Constant Subscriber).—The garden soil, turf, and wood ashes with which you have replaced the old soil of your Vine border is good. Thoroughly mix the top-dressing of decayed stable manure with it immediately. When new roots have become abundant in the new border then you may apply the top-dressings of manure with advantage. The canes or rods should be at least 3 feet apart; if they are closer together remove some of them. New canes should also be trained up at the rate of three or four a year. This is done by cutting off the old canes close to the bottom spur, and with your rich new border new canes laden with a full crop should be had in two years. Take especial care to crop lightly for a season or two, in order to afford your exhausted Vines the full advantage of rest and fresh soil. When early forcing is practised a flue only 15 inches from the stems would prove injurious to them. Twist haybands closely around the stems and they will sustain no harm. We have twice seen Vines killed through neglecting this simple precaution.

Chevel and the stems and they will sustain no harm. We have twice seen Vines killed through neglecting this simple precaution.

CHRYSANTHEMUMS SPORTING (C. C.).—Chrysanthemums occasionally produce sports, or two colours on the same plant, and especially the Cedo Nulli varieties, but such an occurrence as you quote is not very common.

POMEGRANATE NOT FLOWERING (C, J, P).—The specimen should be induced to make short-jointed wood in a very light greenhouse, and in summer place the plant in a hot sunny position out of doors, shading the pot, so that the growth becomes matured, and it must not be pruned in the winter. Old plants usually flower more freely than young ones.

THE CELINE STOCK FOR ROSES (Ignoramus).—The Celine stock is a very robust, strong-growing, Hybrid Bourbon summer Rose of a pretty pink colour, in no way related to the sub-evergreen Tea Noisette Céline Forestier. The Celine was first introduced as a stock by Mr. Cartis, now of Torquay, some forty years since, and is much used now as a rootstock on which to work the strong-growing Teas and Noisettes not congenial to the Manetti.

HOT-WATER APPARATUS (A Young Beginner).—We have had no experience of the apparatus you mention.

ABORTIVE ACORNS (W. H. W.).—The objects you sent are the "cups" of abortive acorns of the Turkey Oak.

of abortive acorns of the Turkey Uak.

NAMES OF FRUITS (E. Bonner).—1, Marie Louise; 2, Maréchal de Cour;
3, Van Mons Leon Leclerc; 4, Doyenne du Comice. (Old Subscriber).—1,
Beurré Diel; 2, not known; 3, Swan's Egg; 4, Norfolk Beefing. (S. M. & A.).
—1, London Pippin; 2, Golden Russet. (E. H. A.).—1 and 4, Trumpington;
3, Cartisle Codlin; 7, Hollandbury; 9, Nelson Codlin; 11, Cellini; 12, White
Doyenné. (J. Farrow).—1, Duchesse d'Angoulème; 2, Beurré Diel; 3, Vicar
of Winkfield. (E. B.).—Probably a small specimen of Vicar of Winkfield.
(Subscriber).—1, Kentish Codlin; 3, Golden Noble; 3, Braddick's Nonpareil.
The others not known.

NAMES OF PLANTS (A. R. F.).—The plant with narrow leaves is Panicum variegatum, the other is Selaginella Martensii variegata. (C. J. P.).—I is Begonia Freebell, the other is probably Metrosideros angustifolius, a native of the Cape of Good Hope, that requires a greenhouse temperature, and a soil composed of peat, loam, and sand.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

THE FATTENING OF CATTLE OF FULL AGE.

On the 14th and 21st of August last we gave the subject of summer grazing of cattle full consideration in these columns. It is now our intention to describe the best method of feeding and fattening cattle of full age—that is to say, of four years and upwards. Although the practice of feeding cattle fat for the butcher at from two to three years old is now much in fashion, yet there is still a desire to follow the old practice of fattening bullocks of full age. This is particularly the case upon the home farms of noblemen and gentlemen, many of whom take

great interest and pleasure in breeding the choicest animals of the sort best adapted for the soil and climate of the district in which their estates may be located—not only for profit, but some are desirous of fattening cattle for exhibition at the metropolitan and Birmingham Christmas shows, as well as at the various local meetings in different parts of the kingdom at other times of the year. Now, many young men are continually coming forward as home farm managers, and are wishing to emulate others in their calling; we therefore propose to lay before them for their benefit the best practice and methods of feeding cattle—not only in the past, but referring to all the latest improvements in the art of fattening up to the present time.

In selecting our breed of cattle for profitable feeding there is no better plan than to select the best-shaped animals of the blood peculiar to the county or district in which the home farm is situated, at the same time taking into consideration the requirements of trade and the markets where the cattle will be most likely sold. When the object is to feed animals for prize competition regard must be had to the class or breed of stock in which they are intended to compete, and this applies to the conditions of most of the large exhibitions, but not to the local shows wherein various breeds compete together. In the latter case it is important to select stock of the highest quality of moderate size, such as the Devons in the south of England, and the Aberdeens in the north or in Scotland, for these breeds when exhibited in competition with the larger animals, like the Shorthorns or Herefords, will usually stand before them in the estimation of the judges, supposing they are of equal quality in flesh and fatness. In selecting stock for profitable feeding on the home farm the animals should be well bred and in good condition, and it is also a good plan in purchasing ten or more bullocks from a drove in the fair or market to select the best animals, for the best bullocks will generally become fat the quickest. After selecting them as carefully as we may, some of the animals will not make such good progress as could be desired, and may be probably not exactly healthy in some respects. These, as soon as noticed, should be rejected and sold for what they will fetch, as it does not answer to continue feeding animals at full head if they do not credit their keep. The best way we have found to obtain profitable feeding stock is to select them in the month of October, when the markets are often over-supplied with animals just beneath the quality required by the butchers. Under such circumstances they are sure to be purchased at a moderate price, and being forward in condition will pay for fattening much better than commencing with animals in poor condition. Worked oxen generally pay well, particularly if they are of the Devon or Sussex breed, these being the principal stock which are now used for working on the land; if, however, they happen to be in rather low condition they must be fed very moderately at first with the superior food, such as oilcake and meal, and be gradually advanced by a steady increase of the allowance of food as time goes on, and when half fat they may then be fed with the full allowance, which we will presently describe, until they are sold.

Having selected the cattle for feeding, whether for the ordinary markets or for competition at exhibitions, it is of the utmost importance that the accommodation for the bullocks should be of the best character, but unfortunately in too many instances this consists of only yards and sheds or stalls; but neither of these are equal in advantage to boxes where the animals can be always comfortable with plenty of room to move about and lie at case in any position when taking their rest. The question of manure also requires consideration, as it is an important factor in considering the advantages of cattle feeding, because in some counties the feeders are satisfied if they do not lose by feeding the stock, and can only obtain a quantity of valuable dung. We, however, say to the home farmer, Yoz must not, and you ought not to be satisfied with such a result, seeing that the practices and experiments which are numerous exhibit a good profit upon feeding, as well as leaving a valuable heap of dung in addition. In our practice we have for the past twenty-five years used all our old

corn barns for feeding cattle in, the accommodation being boxes about 10 feet or 12 feet square, with the dung accumulating under the animals, and the fittings of the boxes being only divided by larch fir poles at a trifling cost, and removable. In some cases we still fill the barns with corn at harvest time, and thrash the crop soon after, and in time to put in the cattle for winter and spring

fattening.

We will first consider the method of feeding for profit on the home farm, and for this purpose it is well to select some of the larger breeds like the Shorthorns and Herefords, or their crosses, for the crosses often prove more growthy and make heavier weights for age than the pure-bred stock. On first commencing to feed the animals in the boxes with roots and artificial food, it is important not to give more food, especially of cake or meal, than the animal can assimilate and convert into profitable beef. At this time it is best to feed the bullocks three times a day with roots, cake, and meal, the first bait at 7 A.M., next at midday, and last at 5 P.M., and the quantity of Swedes not to exceed 70 fbs., or of mangold 60 fbs. per day, mixed with 4 fbs. of oilcake and 2 fbs. of meal, the roots being cut with a Gardener's cutter, the meal strewed over and mixed in the skep before placing in the cattle trough, at the same time having always access to rock salt. We prefer that the cattle should receive their fodder of sweet-wheat or oat straw in the rack ad libitum. the residue to be used as litter for the boxes animal can assimilate and convert into profitable beef. At this in the rack ad libitum, the residue to be used as litter for the boxes. In the event, however, of straw being a scarce article on the home farm, as it often is where pasture land prevails, the straw may be cut into chaff, the roots pulped, the meal and all being mixed together as pudding. Our object in using straw in preference to hay is because it is cheaper, and supplies enough nutriment in conjunction with the liberal allowance of the superior food, and our experience justifies this practice. The analysis of straw by Dr. Voelcker also shows that straw is when cut early almost a partitions as ordinary negative hay. Int. Vocicies also shows that straw is when cut early almost as nutritious as ordinary pasture hay. As a matter of economy there can be no question about it, for a bullock properly fed as above stated will give a weekly improved value of 10s. on the average. In case hay is used instead of straw it will make a considerable difference in the improved value, in consequence of hay being dearer than straw, and leave only a diminished result of a week's feeding, besides which the animals will digest their food better and will not be subject to the drawback of ill health, which is sure to delay the progress of fattening. When the animals are within to delay the progress of fattening. When the animals are within six weeks or two months of the time when they are intended to be sold we find it better to feed with nearly the same total quantity of food as above stated, but only twice a day instead of three times, because it gives them more time to take their rest and sleep, which when they are nearly ready for sale very much facilitates Let us now consider the question of feeding cattle for exhibi-

tion. Where cattle are purchased for the purpose it is well to select animals as nearly ready for the butcher as possible, and particularly to select those which have laid their flesh on evenly, have a firmness of flesh with a soft mellow touch of the skin, and then to feed them carefully for ten or twelve months afterwards, and to use a little of Bowick's flavouring spice to assist digestion, and as the time goes on to reduce the food a little as regards roots or green fodder, continuing the artificial food with regularity. Even after proper feeding and careful housing it is time only that will contribute to success on the day of exhibition. There is yet another plan which in some respects is better than that which we have stated-viz., to breed the stock on the home farm, and let the calf be fat, then a fat yearling, and fatter still at two years old. This plan will give you the best and heaviest animal that can be produced at any given age, the only difference being, that we never can tell whether the animal will lay on the meat evenly until after it is two years old, whereas in purchasing for fattening the bullock shows its character and capabilities by its handling

and outline.

WORK ON THE HOME FARM.

Horse Labour.—There is a considerable acreage yet to be sown with wheat whenever the weather proves open and favourable, and even upon the driest soils the seed time has been very much delayed. At the usual period of wheat-sowing the fodder crops such as trifolium, vetches, rye, &c., had not been done owing to the lateness of the harvest; therefore the delay has been so great that, except under the continual action of ploughing, &c., by steam, it has been found impossible to get the wheat drilled at the usual period. There is not only the portion of wheat to be sown after roots fed off or stored away, but also a portion of the fallow break, as well as some of the clover ley land still to be sown. The snow and frost lately has still further interfered with the work of the home farm. There are, however, so many kinds of work in arrear that at every interval when wheat-sowing cannot proceed other work must be pushed forward before winter sets in Faller slowed when the land in Aller 1. in. Fallow-plough where the land is tolerably free from couch, but where it prevails to a great extent it is better to rafter-plough the land, and in the first open weather in the spring to run the rafters back, or what is called backstetch the land. By this plan the couch, instead of being buried deep by fallow ploughing, is kept near the surface and the more easily dealt with when the

first dry weather occurs in the spring. There is, however, always work for the odd horse or horses at this period of the year; for not only is it requisite to employ them upon certain work necessary for keeping the farm premises in order, but the roadside earth, ditch cleanings, &c., should be carted to heaps in readiness for use at a future time. After it becomes mellow and decayed in heap it serves for various purposes, such as the bottoming of cattle boxes, pigsties, and where there is a farmyard it should be laid for the dung to be made upon it. In the same manner cattle sheds and yards should have earth placed at bottom to absorb the liquid manure and add to the bulk of the compost, to absorb the liquid manure and add to the bulk of the compost, for the earth does not rob the dung but takes up and utilises that which would otherwise be lost. Some farmers object to using earth in this way, saying that it distributes the seeds of weeds; but this argument will not hold good if the compost is applied to pasture or park land, as the seeds of weeds will not grow there like they do upon the arable land. Strictly speaking we have never found that earth used in this way does distribute weeds, because in the act of usage and the heating of the dung in heap

their power of vegetating has been destroyed.

Hand Labour.—During the late snow and frost this has been restricted to indoor work, such as winnowing corn, &c., preparing roots for the cutter for the shepherd and cattle man. In all cases where any considerable number of cattle are kept a small engine of four-horse power will be found useful for cutting the roots, crushing or grinding corn, and cutting chaff either of hay or straw. Where a lesser number of animals have to be fed upon the home farm horse gear will be found a good substitute on a small scale. Either one or the other is almost imperative, particularly as in many districts women or boys cannot be obtained for the light labour upon which we used to employ them. The crop of wheat is so bad in many instances that it will scarcely pay for threshing, winnowing, &c.; in this case the crop as harvested may be cut into chaff and used for feeding cattle, &c., in conjunction with roots, and thus save some expenditure in cake. In various instances we and thus save some expenditure in cake. In various instances we find the corn not only so thin and light after threshing but also in such bad condition that it cannot be ground into meal, but it is equally available when crushed by Taylor's and other crushing machines for feeding in conjunction with cake and roots pulped. The barley, too, in various cases is but little better that the wheat for mealing purposes, and when threshed and screened and looking like a fair malting sample, is often rejected by the maltister as we find that from 25 to 45 revents will not warretter. maltster, as we find that from 25 to 45 per cent. will not vegetate in the malting process. In consequence maltsters are buying barley in the malting process. In consequence maltaters are buying barley from France and other continental States, which they say answers their purpose much better than the English growth. The short crop of roots this year, especially of mangolds, will necessitate severe economy, which may prove a useful lesson to the home farmer, because too many roots are often given to pregnant ewes, or even dairy cows. Every endeavour must now be resorted to for the purpose of eking out a seriously deficient crop of roots, and the use of our inferior corn ought certainly to be made an important factor in the process of feeding all the stock made an important factor in the process of feeding all the stock of the farm which usually consume a portion of the cereal or pulse crops. The lambing folds for the Dorset down ewes should now be made, and a spot upon rather sloping ground should be selected for it in a sheltered position facing south or south-west.

POULTRY IN FROST AND SNOW.

WINTER is again upon us. It is but little more than six months since we were writing about the management of chickens in frost and snow, and again we have a cold and white world. We will give a few hints how to keep the adult birds comfortable at this season. Fowls do not dislike dry frost; indeed, when the air is clear they seem to enjoy it. We have often observed that birds of the year which have caught cold and seemed to stand still at the damp fall of the leaf, as soon as frost sets in become bright and hard in feather, grow again, and shake off their maladies. Some of our own cockerels which roost in trees seem particularly lively, and crow at intervals through moonlit nights. Frost, fog, and snow are however most detrimental to all poultry. The chief points for a poultry keeper now to look to are good shelter. chief points for a poultry keeper now to look to are good shelter and good food.

Under the heading of shelter various points require consideration. To begin, birds must not be in draughts at roost. We are great advocates of ventilation—indeed, we often let birds of our own roost in trees all the winter, or in sheds entirely open on one side, but then they are out of cold currents of air whistling through cracks. Perches should be low, and the ventilation arranged well above the heads of the birds. Then in their yards they much enjoy a sunny corner. A very little paling, or even a high turf bank, will give them a place where they can enjoy hours of sunshine at a

be supplied thus:—As soon as snow has fallen a way should be swept from the house to the most sheltered corner of the run, and here the birds should be fed. Snow brings on violent dysentery if eaten, and care should be taken not to throw the food among it, and to supply plenty of water. Iron troughs are the best drinking vessels in winter, being less liable to crack, but whatever vessels are used they should all be emptied at sunset and refilled in the morning.

Food must be liberal and nourishing. When the ground is hard the usual animal food of poultry is not procurable, they must therefore have some substitute for it. A little minced liver daily does them much good, and, averse though we usually are to stimulating foods, we now mix some Spratt's food in the first meal. It is not a bad plan to pour some boiling water overnight on a pan of this food, leaving it in soak all night, and then the first thing in the morning to mix in barley meal with it till it is of the proper consistency to make crumbly balls, such as we have often described. The last evening feed should be of wheat or maize; grain long continues to give warmth to the system.—C.

BIRMINGHAM POULTRY SHOW.

The thirty-first Birmingham Show opened on Monday last. The judging took place on Saturday, to which life members are admitted, and others who are willing to pay 10s. The attendance on that day is naturally scanty, but all the more opportunity is given to fanciers to enjoy the Exhibition quietly, and to form a correct idea of its special features. The Show of 1879 will be memorable for some great improvements in arrangement. The poultry annex has been quite transformed; much glass has been introduced into the formerly dark roof, and in lieu of the wooden tiers of pens which so obscured the light the ordinary light wire pens are used throughout. As we have never shrunk from plainly expressing our opinion of the ill arrangement of some details of this Show, specially the lighting and ventilation, we are glad to hail this large instalment of improvement

hail this large instalment of improvement.

Brahmas as of late years at Birmingham usurp the first place once held by Dorkings. Darks come first and number 157 in the four classes. These are on the whole well represented, there being twenty-six cocks, forty-seven cockerels, twenty-six hens, and fifty-eight pullets. A comparison of the awards here and at the Palace will illustrate the glorious uncertainty which has taken the place of sound judgment as far as this breed is concerned. We have noted below in many instances how the birds here shown stood at the Palace, but a few general examples may not be out of place. The cup cock at the Palace had here to put up with of place. Ine cup cock at the raiace had here to put up men very highly commended, three birds which he had beaten ten days ago being put over his head. The cup cockerel at the Palace is here quite unnoticed; the second Palace hen is also entirely passed by, while the second and fourth Palace pullets have only highly commended and commended opposite their respective numbers of The £10 cup is here awarded to a cockerel that in the opinion of most fanciers should not have been noticed. There are many most fanciers should not have been noticed. Inere are many better birds in his own class, while the winners in the three other classes are also superior to him. It will probably be his turn to be unnoticed next week at Hull, unless indeed the award be "endorsed" there by the Judge. We would suggest that at the great shows next year some practical fancier be invited to make the awards in Dark Brahmas. This plan has worked well in other revisitions when not let Brahmas man have a change? Cooks the awards in Dark Brahmas. This plan has not been a chance? Cocks.—varieties, why not let Brahma men have a chance? Cocks. are that he is hocked, has a few white splashes at side of breast, and has a comb which, though small, points upwards at the back. He was closely pressed by third (Ansdell), a massive bird with fine head and ample leg feather, but not quite deep enough in marking and somewhat out of condition. This latter point probably turned the scale against him. Second (Kendrick) though good in general shape and colour, has a round back and a comb that should in our judgment have excluded him from the prize list; he was unnoticed at the Palace. Fourth (J. Wood), the cup Palace cockerel of 1878, small and so yellow in back that the award is to us unintelligible. small and so yellow in back that the award is to us unintelligible, after first and third we liked 22 (Lingwood), the winner at the Palace; he is here in better condition generally, but seems to have lost leg feather a little. 11 (Comyns) highly commended, good in shape and colour but heavily hocked; 14 (Norris) small but of fine quality, and 24 (Newnham & Manby) very highly commended, rather dark and not quite out yet, but otherwise a good bird, struck us as being the pick of the rest. Cockerels.—£10 section cup (Ansdell) an awkward-looking bird in bad condition, with both wings out. uzly hocks. legs too close together, hackle slightly wings out, ugly hocks, legs too close together, hackle slightly twisted, and has a tendency to brown on shoulders and back; his only good points were his fine head and comb and his large size. Second (Lingwood) a nearly perfect bird with a somewhat mossy saddle and perhaps too short in back; he should have won easily, while we should have placed same owner's third-prize bird second. This is, we think, the second Palace cockerel; his comb seems to be going rather coarse, and his saddle also is mossy, but he is otherwise a grand bird. Fourth (Hall) a narrow bird of no substance; fifth (J. Wood) a hocked bird with white in tail and mossy saddle, but of fine carriage. We should have placed 45 (Shuter),

good shape and colour and fine comb, third; while amongst the others we noted 30 (Holland), very highly commended, a shapely bird of the short-legged type, and 50 (Ashworth), very highly commended, a large and well-formed cockerel. In both cocks and cockerels coarse combs were far too prevalent, while amongst the noticed cockerels we saw with surprise several with distinctly red or brown shoulders. Hens.—Cup (Clarke) a medium-sized hen of good clear type of pencilling, not quite moulted out yet, which may account for some little irregularity of marking at top of breast and on wing. Second (Lingwood) a grandly-made large hen, even in colour and marking, but not quite so clear as the winner; we should have placed her first as being of the true type to breed from for both sexes. Another of similar pattern was (same owners), 96 highly commended, fourth at Palace. Third (J. Wood) a well-marked bird of the pure grey type, inclining to smallness, and just a trifie deficient at top of breast. Fourth (Peake) beautifully clear on breast, but showing a very objectionable dark brown tinge on the back and wings. 76 (Norris) second Palace, here unnoticed, excellent in marking, though not quite satisfactory in shape. 94 (Ansdell) worth a very highly commended. This was an extremely good class, many of the merely commended birds being of first-rate quality. Pullets.—Cup (Percival) the Palace winner, again in her right place. She is of fine size and shape and good pencilling, a very different bird to her yard mates, fourth and fifth, which were both of the mealy type which Mr. Teebay seems so much to admire. The fourth particularly was quite unworthy of her position. Second (Wheadon) was the third Palace pullet; she is of good shape and well marked in a way now somewhat out of fashion, but sound none the less in a way now somewhat out of fashion, but sound none the less in a way now somewhat out of fashion, but sound none the less in a way now somewhat out of fashion, but sound none the less in a way now somewhat out of fashion

Lights are not so numerous as the Darks, but all the classes are good. The cup cock (R. P. Percival) is a small and very shortlegged bird, almost dumpy; his shape is good, his foot feathering very fine, but, of course, accompanied by hocks. We much admired the second cock (A. Ogden), a large upstanding bird; a thorough Brahma, with good head, well-marked hackle, and soft full leg feathering. The third (G. B. C. Breeze) cock is not unlike the first in shape, with darker hackle marking, and fine shape of back. Fourth (H. Tomlinson) a big bird, with good leg feathering, but deficient in cushion and rather yellow. Mr. Ward's commended bird struck us as being good, though out of condition. The cup cockered (P. Haines) is a pretty bird with neat head and comb, and good ground colour and hackle marking. Second (P. Haines) a taller type of bird and well grown; he might be whiter. Third (Mrs. J. T. Holmes) apparently very young; good all round. Fourth (S. Lucas) good in colour and marking, but far too narrow in body. Fifth (Rev. G. S. Davies) a pretty bird in head, and fine in foot feathering. 199 (Williams) a good bird, which we should have put in the list. In hens the cup (Mitchell) goes to a splendid bird all round; not very large, but good in every point, with specially fine cushion and foot feathering. Strange to say, we hear she was unnoticed at the Palace. Second (While) another very nice hen; good all round. Third (Onions) pure in whiteness, with well-striped hackle, not much foot feather. Fourth (Ive) as large as any; very fine in fluff. The hen class was a large and generally good one; many nice birds in it had to be content with admiration and no cards. The cup pullet (Haines) is a lovely shapely bird, more hocked than we like. Second (Breeze) attractive in colour, and good in size; she held her wings quite loose when we saw her. We did not much like the third (Tomlinson). She is good in back and hackle, but much hocked, and not fluffy enough. Fourth (Tedd) not a strking bird in any point, but fair all round.

Sp.nnish.—Cocks: Cup (E. Jones) an easy win in a poor class of four. His face and earlobe are long, broad, and of good quality. Second (Bull) rather full and rough, round eyes, and not through his moult yet. Cockerels.—First (J. Walker) a fine bird, with good long earlobe, perhaps a little rough in quality. Second (Alsopp) shows red over eyes, and for that reason should have given place to 1221 (Walker). The class had only thirteen entries, and, except the birds noted, was of no great merithens.—First (J. Woods) a fairly good bird, as also was second (Winfield & Davies), but there were only five entries in the class, and two were absentees. Pullets (five entries).—Cup (J. Woods)

looked washed-out in face, pale in comb, and rusty in plumage; should, we think, have given way to second (Walker), which was a fine-sized bird in the pink of condition, with a beautiful quality of earlobe.

Dorkings .- Mr. Burnell's grand Dark cock appeared here again and again, as at the Palace, took the cup; after him the class of old Dark Dorking cocks is by no means equal to that of the Palace. Second (Leno) is rather too dark a bird in colour, but he has a good comb and white feet. Mr. Drewry's very highly commended cock is a large bird and good, barring his lopping comb. Mr. Butler Smith's, too, is a good bird, his weak point comb. Mr. Butler Smith's, too, is a good bird, his weak point being feet. Cockerels are hardly equal to the Palace. First (Miss J. Milward) a fine and good bird in comb and colour, but his feet might well be much whiter. Second (Mrs. Troughton), pretty short-legged bird that has so often won. Third (White) a very dark bird with good comb and feet. Fourth (R. Gladstone), a large bird with poor comb and horrid dark feet. Messrs. Smyth show a large sprightly cockerel with good feet, but spoilt by a lonning comb. Mr. Butler Smith's an immense hird but with lopping comb. Mr. Butler Smith's an immense bird, but with a gouty toe. The cup Dark hen (R. Gladstone), is a grand bird with short legs and rice white feet. Second (B. Smith) another good hen, the cup bird of last year, we believe. Third (White) rich in colour, and little behind the other winners. (white) fich in colour, and little benind the other winners. Pullets have the prevailing fault of dark feet. First (Bell) a very large bird, but too long on the legs. Second (Drewry) large again but very dark in feet. Third (Mrs. Troughton) a pretty pullet, though not good in comb. We like Messrs. Smyth's highly commended pullet, we think one of the Palace winners, and Mrs. Hind's highly commended bird has white feet. The Silver cocks make a small class, and we cannot agree with the awards. First (Cranston) is a short-legged well-shaped bird, but the whole of his neck hackle 13 ticked in a peculiar way like a Silver-spangled Hamburgh. Second (Demison) is about the worst bird in the class; he has a horrid comb and a grizzled breast. Cockerels make a large class, but the greater number of them are far too heavily striped in neck hackle. First (Cranston) is all round the finest cockerel, but he has much white on breast, and his fifth toes are swollen. Second (Lady white on oreast, and his fifth toes are swollen. Second (Lady Bagot) we consider a great mistake; the cockerel has a very dark hackle and a broken fifth toe. Third (Cresswell), not very large but short on the leg, and for colour the best bird in the class. The two winning hens (Burnell and Cranston) are good in size and The two winning hens (Burnell and Cranston) are good in size and form and white in feet, but both have bumble feet. Pullets are a pretty good class. First (Smalley) a fine bird, but dark in feet. Second (Burnell) a large pullet, which might be better in colour. Third (Cresswell) the very-white-footed pullet which was first at the Palace Show; 482, very highly commended (Cresswell), also a handsome bird. Cuckoos though few are better than usual, but the cup bird (Howe) is a wonderful specimen. How such a judge as Mr. Dixon could give a cup to such a creature over the heads of such good Whites we cannot conceive. He is over the neads of such good whites we cannot conceive. He is an evident mongrel, long-legged and breastless, with Cochin head, tail, and voice, single comb, bad marking, and small feathers down his legs. We fancy one of his parents must have been a Plymouth Rock. Such mistakes are very disheartening to breeders of honest Dorkings. Nearly all the fanciers of the breed were indignant, and some of them wished to make a protest on the ground that the hird is not a Dorking at all, but were informed that it was not the bird is not a Dorking at all, but were informed that it was not open to them to do so. The second (Playfoot) Cuckoo cock is a handsome short-legged bird, and both the winning hens (Countess of Dartmouth) are very good. The four White cocks are four as tine birds of the kind as we have ever seen together. First (Logan) very large and good, but too yellow. Second (Cresswell) the short-legged very white Palace cup bird. The other two (Pilgrim and Countess of Dartmouth) both deserved their high commendations. The first (Logan) cockerel is the Oxford cup bird, short-legged and set. Second (Pilgrim) a very pretty bird, with a beautiful comb. In hens the first Palace bird (Cresswell) again wins, looking well and large. Second (Cresswell) a square good young hen. There is but one first-class bird (Logan) among the four pullets, which wins; second (Pilgrim) is very fair.

Cochins always hold their own at Birmingham. Together with

their Langshan cousins they number close on five hundred pens. Mr. Hewitt's powers seemed sorely taxed to get through the task of judging them; he considered the light insufficient for the purpose, and so had the majority of the birds carried by assistants from their pens. We watched the men carrying the birds about roughly and awkwardly, and saw their frightened looks on being thrust hurriedly into fresh pens, and much doubt whether the best birds will in all cases have been thus discerned. The £10 cup for the hest Cochin in the Show goes to the wonderful Palace cup for the best Cochin in the Show goes to the wonderful Palace Partridge cockerel, Capt. Heaton's purchase at £68. In Buff cocks, first (Rigg), is the grand Palace winner, which we need not describe again. The second Buff cock (Procter) is of a very even describe again. The second Buff cock (Procter) is of a very even bright yellow colour; he has a black tail, and is not well through the moult. Third (Procter), a very pale bird, mealy on the wing, very good, however, in foot-feathering. We preferred 598 (Percival), a thorough Cochin, second, we believe at the Palace; also another grand bird of Mr. Percival's, 611. Cockerels make a very bright yellow colour; he has a black tail, and is not well through the moult. Third (Procter), a very pale bird, mealy on the wing, very good, however, in foot-feathering. We preferred 598 (Percival), a thorough Cochin, second, we believe at the Palace; also another grand bird of Mr. Percival's, 611. Cockerels make a very large class. It struck us that a great many of them have very large class. It struck us that a great many of them have very large class, which we look upon as a defect, taking off.

Hamburghs.—The cup Golden-pencilled cockerel (Whitaker) has good comb and colour, but poor tail; his lobes are too large for our taste. Second (Gilroy) a good bird, rather high in comb. Third (Rawnsley) good in comb, but too much contrast between the shades of his neck hackle and his saddle. The Duke of Sutherland's highly commended bird has a splendidly laced tail. The first (Driver) Golden-pencilled pullet is a gem, most beauti-

from the look of dignity which a Cochin should have. cockerel (Swindell) is good in shape and feather and brilliant in colour. We do not at all like the second (Stainton); he has ugly reddish-brown wings, though his shape is undoubtedly good. Third (Cockroft and Ashby), a deep-coloured bird, good in comb and shape; his wings not light enough. Fourth (Pye) of a lovely bright yellow colour. Another pretty bright-coloured bird is fifth (Tomlinson); we do not like the black and white in his tail. The class of hens is indeed a wonderful one; the cup bird (Procter) is not very large, but a marvel of shape and feathering. Second (Bloodworth), a larger bird, but not in such condition as the first, and not so fine in foot-feather. Third (Procter), a nice canary-coloured bird. Fourth (Percival), an immense hen. We like 657 coloured bird. Fourth (Percival), an immense hen. We like 657 (Chatworthy), claimed at twelve guineas; indeed half the hens in the class are worthy of prizes. The cup pullet (Procter) is a rich, deep, even Buff. Second (Darby), is a very pretty pullet, good all round, a shade lighter and brighter than the first. Third (Lady Gwydyr), a young-looking bird, canary-coloured, shapely and fluffy. Fourth (Tomlinson), a large bird, promising to make a fine hen. Fifth (Procter), good in shape and feathering but not large. Partridges quite hold their own, though in numbers they do not come up to the Buffs. First (Heaton), a fine cock all round, though we have seen better. Second (Heaton), a very grand old though we have seen better. Second (Heaton), a very grand old bird but looking tired. Third (Wood), remarkable for fine foot feathers. The cup cockerel (Heaton) is the wonderful Palace bird which we need not describe again; the only part of him which we do not think perfection is his head. Second (Tudman), a good bird in colour and comb. far below the first in fuffiness. Third bird in colour and comb, far below the first in fluffiness. Third (Sharpe) is short in neck hackle at present, but we liked his lower parts better than the second. Fourth (Macrae) too much hocked, but fine rich black in fluff. Captain Heaton has a well-shaped cockerel in pen 788. In the hen class we observed an empty pen (Mrs. Forsyth Grant's), and a ticket to the effect that the bird intended for it had been rejected for being sent contrary to a regulation in a divided basket; we wish this rule were altered. The cup Partridge (Wood) hen is a large bird, lovely in pencilling, but not well feathered on legs and feet. Second (Sharpe) a fine bird in form and size, inclined to be grousy in colour. Third (Wood) small, good in shape and pencilling. 794 (Wiggins) a massive reddish hen. There are several other hens in the class splendid in form though not sufficiently clearly pencilled to win.

The first (Wood) pullet is a thorough Cochin in shape and good

in breast pencilling. Second (Tomlinson) beautifully bright in colour and clear in pencilling, but loose in wings. Third (Macrae) struck us as a narrow bird. Fourth (Heaton) very large, with small clear pencilling; she should make a splendid hen, though at present a little too long on the leg. The first (Percival) White cock is a fine bird in condition and shape, but has regularly Buff wings, which we consider a fatal blemish. We much prefer the second (Chase), magnificent in breadth and depth of fluff. He is not in bright condition. 853 (Darby) a very fine bird. In is not in bright condition. 853 (Darby) a very fine bird. In cockerels the position of the first and second Palace birds is re-The winner (Ludlow) is the bird we much admired at versed. The winner (Ludlow) is the bird we much admired at Oxford, and which has changed hands at high figures; but we certainly should not have put him before the Palace winner (Darby), which is far larger, and in every point his equal. The White hens are a capital class. The winners (Tomlinson) are both grand hens, with little to choose between them. Many others would in ordinary years have been in the prize list. We thought the pullets better than at the Palace. First (Darby) is the second Palace bird, which we there preferred to her sister, here unnoticed, though there first. In Blacks Mr. Lightfoot's cock is an easy first though there first. In Blacks Mr. Lightfoot's cock is an easy first in his class. Second (Aspden) we do not much like, and prefer Mr. Darby's very highly commended bird; a winner, we fancy, at the Palace. The Blacks were, we believe, judged by gaslight, which may account for some change of position from other shows; but considering this fact, and that some of the classes were partially in dark lower pens and partially in light upper ones, we think the awards were on the whole well made. The first (Darby) cockerel is an easy first, and very handsome. He was, we think, third at the Palace. Second (Storer) a pretty but small bird. The first (Cook) hen has a fine green gloss, but an ugly comb; second (Darby) in nice condition. The first (Turner) pullet is a beauty, and wins easily. Among the highly commendeds are some very fine pullets, which will make finer hens than are often seen in the Black classes. In the Cochin Selling class we observed a pair of Cuckoo hens, one of them very good for her colour.

Langshans have two large classes, and seem to have been judged

in a way which should please their admirers.

Andalusians.—The first (Jones) pair are fine in form; the pullet well laced, but the cockerel is too red in lobes. Second (Stevens) a large pullet, with a neat and pretty cockerel. Third (Troughton) both good birds.

Hamburghs .- The cup Golden-pencilled cockerel (Whitaker)

fully marked on the tail. Second (Bell) has a pretty comb and rich ground colour. The class is an even one. The winning Silver-pencilled cocks are both nice birds. The first (Beldon) good in comb and figure; the second (Snell) has the best-laced tail. The Silver-pencilled pullets are nearly all very fair, without any one bird being very striking. The first (Beldon) is well barred up the tail.

Any other Variety .--First Mr. Beldon's beautiful Buff Polish, in splendid condition and trim. Second (Gabb) a curious large dark pair of Asiatics, called "Mandarins." The cock has points of The cock has points of resemblance to a Dark Brahms. The hen reminds us of the illustrations of the early imported Cochins presented to the Queen. Third (Bradbury) Plymouth Rocks. Two pairs of fine large red birds, called Tankervilles, are shown. Mrs. Troughton shows a nice pair of Courtes-pattes, and Mr. H. W. Howe some Cuckoo

The first (Hedges) prize pair of Aylesbury Ducks weighed 18 lbs. 11 ozs.; the first (Wakefield) Rouens 20 lbs.; the first (Nicholls) Pekins only 13 lbs. 2 ozs.; the first (Rawson) White Geese 44 lbs. 14 ozs.; the first (Rawson) Grey 38 lbs. 6 ozs.; the first (Gladstone) old Turkey cock 37 lbs. 3 ozs.; the first (Wykes)

first (Gladstone) old Turkey cock 37 ibs. 3 ozs.; the first (Wykes) young bird 26 ibs. 4 ozs.; the first (Kendrick) old hen 24 ibs.; and the first (Lythall) young bird 17 ibs. 8 ozs.

Polish.—These beautiful fowls numbered ninety-one pens in the twelve classes, and as a whole are of very fine quality. Black cocks numbered six. First (Shaw) is a splendid bird in fine plumage, with a very fine large well-formed crest, very free from black. Second (Lecher) a good bird, slightly yellow in crest, which was, however, very good in shape, and the bird in fine condition. 1277 (Broad) commended, is the Crystal Palace winner, a very good bird, but looking rather down in condition. 1278 (Shaw) 1277 (Broad) commended, is the Crystal Palace winner, a very good bird, but looking rather down in condition. 1278 (Shaw) highly commended, a capital bird with a good white creat. In cockerels (seven), first (Lecher) was a splendid bird, grand in creat, large and well shaped. Second (Rawnsley) has a good, large, well-formed crest, fine in shape and in good condition. 1283 (Partington) a well-crested bird, rather small; 1284 (Shaw) good, but the creat a little too much down in front; 1288 (North) a very good high but out of health 1925 (Flady Dattmouth) empty. In good bird but out of health; 1285 (Lady Dartmouth) empty. In hens (six) first (Broad) the well-known hen, Pattie, looking well in spite of age; in size and shape of crest a grand bird, though the crest shows a little too much black in front. Second (Shaw) very good in crest and a fine hen, though perhaps scarcely so good as 1290, belonging to the same exhibitor; this hen had a particularly finely shaped crest. 1294 (North) a very fine crested hen. In pullets (four) first (Partington) is a very handsome bird, very good in crest. Second (Partington) a pretty bird, very globular in crest. 1298 (Shaw) rather loose in crest; 1297 (North) empty. Golden cocks formed a class of seven pens. First (Silvester) is a bird of nice crest, good rich colour, beautifully laced wings but too dark on the breast. Second (Partington) is a splendid crested too dark on the breast. Second (Fartington) is a spiencial crested bird, though rather flat yet; very good in colour and well laced on the breast and wing, will be the best bird of the two in time. 1806 (Burrell) a good coloured bird. In cockerels (nine) a splendid class. First (Silvester) is a richly coloured bird, very good in crest and well laced on the breast and wings; he was first at Oakham last week. Second (Partington) is fine in crest and rich in colour, also well laced, but a little round in the back. 1810 (Partington) a well marked and good coloured bird: 1811 (Dartington) a well marked and good coloured bird: 1811 (Dartington) a well marked and good coloured bird: 1811 (Dartington) a well marked and good coloured bird: 1811 (Dartington) a well marked and good coloured bird: 1811 (Dartington) a well marked and good coloured bird: 1811 (Dartington) a well marked and good coloured bird: 1811 (Dartington) a well marked and good coloured bird: 1811 (Dartington) a well marked and good coloured bird: 1811 (Dartington) a well have a marked and good coloured bird. (Partington) a well marked and good coloured bird; 1811 (Dawson) a fine crested and well marked bird; 1812 (Huish) was, we son) a line created and well marked bird; 1812 (Huisn) was, we believe, the Crystal Palace second; if so, he has not improved aince then. 1818 (Rawnsley) very good in crest and shape, but rather dark in colour; 1814 (Hodson) very good, capital in crest. In Golden hens (nine) another fine class. First (Millner) is a splendid crested hen, but not good in either colour or marking. Second (Boothby) is a good crested hen, exceedingly rich in ground colour, well marked and quite clear in tail, a very hand-some high. 1812 (Marked) a good hart, 1818 (Silecton) to some bird; 1317 (Hopwood) a good hen; 1318 (Silvester) too spangled in marking but good in crest; 1820 (Boothby) a wellspangled in marking but good in crest; 1820 (Boothby) a well-laced hen, good in crest and with scarcely any white in it; the Crystal Palace second. 1319 (Partington) a fine hen, very well laced; 1828 (Partington) a fine crested hen, rather light ground colour. The Crystal Palace third, 1822 (Burrell) the winner two years ago; a very good hen. In pullets (seven) first (Jarvis) is a rich-coloured well-laced bird with a good well-formed crest, a handsome bird. Second (Silvester) is the Oxford cup pullet, splendid in crest, but too dark in colour. 1830 (Rawnsley) very fine in crest, dark in colour and marking. 1825 (Burrell) a good nullet with a pretty crest: 1829 (Dawson) good in crest but round pullet with a pretty crest; 1829 (Dawson) good in crest but round in back. In Silver cocks (eight) first (Burrell) is the Crystal Palace winner, a splendid bird, with a crest grand in size and shape. Second (Burrell) is the second Palace bird, a very good snape. Second (Burreil) is the second raiace bird, a very good bird in every point, excepting a little imperfection in the back. 1332 (Adkins) splendid in crest, well marked, and a very good bird; 1383 (Lady Dartmouth) and 1335 (Adkins) are good birds; 1336 (Bloodworth) a very fine bird; 1338 (Smith) a very fine bird, aplendid in crest, and well marked on the wing and breast. In cockerels (ten) first (Adkins) was very good in crest, clear in colour, finely spangled on breast, and laced on the wing. Second (Bloodworth) is splendid in crest, beautifully laced; a very fine bird. 1343 (Adkins) good; 1344 (Smith) good in crest and a

well-marked bird. 1348 (Burrell) good but young; 1349 (Adkins) well-marked bird. 1848 (Burreil) good but young; 1848 (Adkins) good, excepting a small comb; 1847 (Smith) empty. In hens (six) first (Adkins) which won the cup for the best Polish fowl in the Show is the Crystal Palace cup bird; a beautifully laced very handsome hen, splendid in crest. Second (Burrell) also a very good hen, is, we think, the Palace third; a fine crested well marked bird. 1852 (Lady Dartmouth) a splendid hen, immense in rest; 1853 (Adkins) another very good hen with a capital crest; 1854 (Bloodworth) a very good hen; 1855 (Adkins) a good well-laced hen, very fine crest. If we recollect aright this was second at the Palace. In pullets (twelve) first (Adkins) is a splendid at the Falace. In pullets (twelve) first (Adkins) is a splendid crested bird; good in shape, rather heavy in marking. Second (Smith) is a very good one, very well and evenly laced and with a capital crest. 1356 (Smith) a very handsome pullet, beautifully laced; 1361 (Huish) nicely laced; 1363 (Smith) good in crest and prettily marked; 1365 (Burrell) a good created bird, very well marked; 1366 (Bloodworth) a good well-laced pullet.

Sultans (six) are a fair class. The first (Beldon) much the best;

Sultans (six) are a fair class. The first (Beldon) much the best; both birds being splendid in crest. Second (Shaw) are a nice pair. Third a very good pair, but the cock is not yet through the moult. 1870 (Wright) a very good hen; 1373 (Jenkins) empty.

Malays numbered forty-seven in four classes. In cocks (fourteen) first-and-cup (Lecher) for the best Malay cock is very good indeed, splendid size, good in head, and in fine trim; a good dark bird. Second (Lowe) is a very large, strong-made, black-breasted red bird, good in head, and of capital shape. Third is a very fine streaky-breasted bird, large and of good shape. 1076 (Nicholls) and 1080 (Brooke) are good Whites; 1073 (Copp) and 1075 (Pearce) are good birds; 1071 (Burnell) a good dark Red; 1076 (Michael) a good tall well-shown bird. In cockerels (ten) we think the winner must have run the adult bird hard for ked; 1076 (Michael) a good tall well-shown bird. In cockerels (ten) we think the winner must have run the adult bird hard for the cup. He is a very fine, tall, reachy bird, large and fine in shape; fine also in limb, and of rich dark colour. Second (Fairle) is a very good rich-coloured bird, fine in colour, size, and make. Third (Strugnell) a very good, large, coloured bird; 1087 (Venables) a good bird; 1086 (Ridley) was empty. In hens first (Brooke), which won the cup for beat Malay hen or pullet, is a very good. is a very good, large, dark brown bird, a little marked on the is a very good, large, dark brown bird, a little marked on the breast, &c. Second (Lowe) is also a good large hen, darkish in colour. Third (Burnell) is lighter in colour; a good, large, well-made hen. 1192 (Fairlie) and 1193 (Burnell) are good lightsh-coloured hens; 1194 (Kidley) a good, large, well-shaped bird, darkish colour; 1101 (Strugnell) a large hen; 1104 (Burnell) light in colour; a good large bird. In pullets (ten) first is very good in shape, fine in size, and a good dark brown; second large, good in shape, and dark in colour: third a very good nullet of good in shape, and dark in colour; third a very good pullet of lighter colour; fine shape. 1109 (Ridley) good; 1110 (Lecher) a large bird; 1111 (Venables) dark and good.

VARIETIES.

MR. CRESSWELL requests us to announce to the members of the Poultry Club that his address henceforth will be Morney Cross, Hereford.

THE Marquis of Lansdowne, who is the owner of property near Kenmare, county Kerry, has sent 175 tons of Champion seed potatoes to be distributed among his poorer tenantry for planting for the next crop.

— THE SMITHFIELD CLUB CATTLE SHOW.—The general arrangements for the forthcoming cattle Show, which opens at the Agricultural Hall on Monday next, are completed, and accommodation has to be provided for fifty head of cattle more than last year. There is also a considerable augmentation in the entries in the sheep and pig classes. This increase in the cattle is due to the relaxation by the Smithfield Club of a rule which prohibited the exhibition of any animal at the Metropolitan Show which had been exhibited at any provincial show within a period of one month previous. This entirely excluded the exhibition of any of the stock of the Birmingham and other shows, which will now have an opportunity of competing at the Smithfield Club Show. The prize list of this year has been considerably increased. The Queen will, it is understood, be found as a competitor with the Prince of Wales in the Devon and Shorthorn classes of cattle, but not with the same animals sent to the Birmingham Show, and out not with the same animals sent to the Birmingham Show, and also in the pig classes; and the Prince sends some South Deron and other sheep from Sandringham in competition with the Duke of Richmond. Earl Walsingham, and other Southdown and Leicester breeders. The increase in the demands for space for implements is so great that much difficulty has been found in affording accommodation.

- WE have received from Messrs. Christy & Co., Fenchurch Street, a manual on "Hydro-Incubation," by Thomas Christy. exhaustively. It is well illustrated, and forms, as is stated on the title page, "a guide to commercial poultry farming." This work will no doubt prove of considerable utility to many persons who are intercested in artificial insubstices. who are interested in artificial incubation.

— THE Birmingham cattle and poultry Show, held at Bingley Hall and which closes this day (Thursday) has proved one of

the most successful on record. The following extra prizes were awarded in the cattle and sheep classes:—Silver cup, value £25, given by Earl Howe, for the best animal in the cattle classes bred given by Earl Howe, for the best animal in the cattle classes bred and fed by exhibitor.—J. Merson, Craigwillie, Aberdeenshire. The Elkington challenge cup, value one hundred guineas, for the best animal, to be won two years successively.—H. D. Adamson, Bulquharn, Aberdeen. £100 for the best Hereford.—Mrs. Edwards, Wintercott, Leominster. £100 for the best Shorthorn.—H. D. Adamson. Fifty guineas for the best Devon.—Thomas Dyer, Lytchett, Minster, Dorset. Twenty guineas for the best Longhorn.—Major-General Sir F. Fitywygram, Havant, Hants. £50 for the best Scot.—W. McCombie, Tillyfour, Aberdeen. £50 for the best animal in classes 20 to 25 inclusive.—Mrs. McWilliam, Bucharn. Gartly. Aberdeenshire. Bucharn, Gartly, Aberdeenshire.

AT the same Show Messrs. Webb & Sons, Wordsley, — At the same Show Messrs. Webb & Sons, wordsier, Stourbridge, notwithstanding the very unfavourable season, have a splendid display of roots. Conspicuous amongst the exhibits is a very fine collection of roots grown by Her Majesty the Queen. Webbs' Imperial Swede is largely and well exhibited. Turnips are excellent, particularly Webbs' Purple Top Mammoth and Green Globe. Mangolds Webbs' Colonel North, Yellow Globe, Mangolds Webbs' Roomed Webbs' North, Yellow Globe, Wanneth Long Red Vellow Intermediate Webbs' North Kinner. Mammoth Long Red. Yellow Intermediate, Webbs' New Kinver Yellow Globe, and Yellow-fleshed Tankard are all of fine qua-Yellow Globe, and Yellow-fleshed Tankard are all of fine quality, considering the season. Very fine specimens of Webbs' Green Kohl Rabi command notice. A remarkable collection of specimens of natural Grasses, with Webbs' Challenge White, Square Head, and Golden Drop Wheat, Webbs' Kinver Chevalier Barley, and Challenge White Oats, also a fine collection of Potatoes, Onions, Carrots, and other vegetables assist in making this stand complete.

PIGEONS AT THE LATE CRYSTAL PALACE SHOW.

I COULD not but observe when at this Show the decrease in number of the Pigeon classes, and notably the loss of the four pair classes which in their large handsome pens used to attract so many eyes, and, indeed, were the gems of the whole Exhibition. I was not, however, prepared for the great falling-off which a minute comparison of the catalogues of 1878 and 1879 reveals. In the former year there were 1677 pens of Pigeons; in the present year 1497 pens only, being a falling-off of 160 pens. Nor was this all. The selling class of 1878 was only 98 in number, this year it has risen to 142; showing, in fact, that there are a much greater number of persons who want to dispose of their birds this year than last. I invite attention to the following table, showing cractly how matters stand, asking my readers to bear in mind that not only is there a diminution in almost every class, but that the forty-four additional pens for sale are reckoned in the full number, so that the real diminution reached to upwards of two hundred pens—a significant difference indeed! Is the fancy quite as high-class as formerly? Are there no low tricks connected with it from which high-minded fanciers shrink? Whatever the reasons are, the fact of the deterioration of the Show in numbers and quality remains. I invite a careful study of the following table, which I believe is an accurate one.

Class.	Number. 1878.	Number. 1879.		Decrease.
Pouters		151	43	0
Pigmies		16	6	0
Carriers		172	0	90
Dragoons		212	0	42
Almond Tumblers		22	0	26
Balds and Beards		21	1	0
Other Short-faced Tumblers	33	31	0	2
Barbs		48	0	1
Jacobins		105	0	3
Fantails	61	49	0	12
Nuns		13	0	4
Trumpeters	9	6	0	3
Trumpeters (young)	no class.	11	11	0
English Owls	98	73	0	20
Foreign Owls		16	0	2
Turbiteens	6	none.	0	6
Turbita	114	91	0	28
Magpies	48	34	0	9
Swallows		14	14	0
Archangels		12	Ō	4
Runts		12	Ō	8
Flying Tumblers		14	Ō	6
Short-faced Antwerps	16	l ii	Ó	6
Homing Antwerps		129	1 7	Ŏ
Any other variety		22	8	ŏ
Best collection of four pairs, exclud-			1	
ing Carriers and Pouters	21	none.	0	21
Best pair bred in 1878 or 1879	15	12	ŏ	3
Flying Class of Homing Antwerps		60	ŏ	5

By the above it will be noticed that only one class has greatly increased—viz., that of Pouters—those fine birds which had been too much neglected by English fanciers, and which are perhaps the very highest type of Pigeon; and everyone, therefore, must

rejoice to see them greatly advance. The decrease of Carriers and Dragoons is surprising; that in Almond Tumblers by no means so, as honest minds and kind hearts resent and shrink from shaping poor birds' heads with a wooden machine. If judges would but make colour the point, and head and beak very inferior points, then true beauty would be cultivated and cruelty receive a check. In almost all the classes it will be seen there is a decrease. Swallows and young Trumpeters must not count, as they had no class in 1878; neither can a slight increase in Homing Antwerps reckon much, as they are not so much birds of fancy, or true fancy Pigeons, as birds of usefulness. What are we to say to this great falling-off in the first Pigeon show in the kingdom? The answer is difficult. Are we never again to see such shows in the Palace as in former years?—WILTSHIRE REGTOR.

MR. J. J. MECHI of Tiptree Hall, Kelvedon, Essex, informs us that he will, for the public good, send (on application accomus that he will, for the public good, send (on application accompanied by a postage stamp), instruction for the construction of the "Parson's" or "Front-fire Grate." The tested gain by the use of this grate is an increase of 15° of temperature with a saving of one-third in fuel. Mr. Mechi believes that there are several millions of grates on the wrong principle, hurrying the heat up the chimney instead of into the room, and thus causing an in-draught of cold air—this is especially the case with strong-draw-ing registers. No part of a grate should be of iron, except the thin front bars, for iron is a conductor away of heat, but firebricks are not so.

SOME RECENTLY OBSERVED FACTS REGARDING

Some four or five years ago my attention was first drawn to the fact that queens frequently became useless from the loss of a leg or a part of one, or owing to the paralysis of an otherwise perfect limb. Since then my first impulse on inspecting a hive is to observe whether her majesty has the regulation number of these locomotive appendages. The result is a positive conviction that in almost every case of the failure or loss of the queen there may be found this deformity. I cannot account for it, but there is the fact, and I commend it to the attention of every bee-keeper as of great importance. By keeping a sharp look-out the disabled queens may be discovered and superseded before the stock has seriously suffered. Occasionally the deformity is but slight, only the claws of one foot being wanting, in which case the queen may be still able to balance herself as in the act of laying eggs; but more frequently so much of the limb is gone that she cannot do this, though quite able to walk about, and in the worst cases she cannot even hold her place on the combs, but wanders about the floorboard, generally ending by crawling out as if resolved to rid the stock of her useless presence. The deformity is not confined to queens of any particular age, as I have in some cases had to destroy virgin queens for the same reason. Neither is it more common in bar-frame hives, as if it might have resulted from common in our-traine inves, as it is might have resulted from accidental pinching. It is common enough even among imported queens just arrived. In some cases the portion of the leg left turns black and rigid, while in others it moves in a natural way. I can easily fancy queens caged amongst hostile bees having their legs or wings torn through the meshes of the cage, and

indeed have observed this more than once, but the most of the cases I have observed were entirely apart from such a cause. I have also frequently discovered bees encasing their own queen and hunting her in a hostile manner about the combs; but in such and hunting her in a hostile manner about the comps; but in such cases I generally discover her dead body thrown out within a day or two, generally, however, maimed. Whether the result of hostility on the part of the bees or of a hitherto unknown disease, the facts are as I have indicated; and, as I have never observed any reference to them by any other writer, I would express a hope that bee-keepers will give attention to the matter and lay the result of their observations before us.

result of their observations before us.

It has hitherto been generally supposed that if, by stimulative feeding or otherwise, we can coax a queen into laying eggs, we can depend on getting brood reared. Much to my chagrin this fallacy is now exploded. During the late autumn, as a result of my experiments in pollen feeding, I came to the conclusion that as both larvæ and adult bees required nitrogenous food, no brood could be record without rollen and I think my experiments. be reared without pollen, and I think my experiments have fully demonstrated that. But it rather took me by surprise to discover that in some of my hives that reared no broad for many weeks, the queens were steadily laying all the time. I had been feeding some stocks on flour, candy, and syrup, and others on syrup alone. The former had several cards of broad even into November, while The former had several cards of brood even into frowning, while the latter, though plenty of eggs were always found in the combs, never reared any. Day after day for weeks the eggs were seen, frequently two or three in one cell, but never a grub. The stocks were fairly good and quite able to maintain a hatching temperature. I came to the conclusion that as the eggs hatched out and the larves. died from want of pollen food, fresh eggs were laid in the same cells, and thus my poor queens had been kept laying every three days as many eggs as others were doing with so much better results in three weeks. Regarding it as certain that such treatment would inevitably "play out" the best queen long before her natural term, I secretly resolved to abandon mere syrup feeding for the future, unless at a time when natural pollen is being gathered. But here some will object that there might be plenty of stored pollen in the hive, in which case the syrup would be sufficient. It might for a party short time, that is, so love as the syrup came it were short. wery short time—that is, so long as the syrup came in very slowly indeed; but as soon as syrup or honey is stored in any quantity, the stored pollen is entirely covered up, the bees themselves not knowing in which cells to seek it. This is even more likely to be the case in autumn than at any other season, owing to the instinct of the bee leading it to store its supplies right in the brood nest. of the bee leading it to store its supplies right in the brood nest, where the pollen is generally found. In such a case I have no hesitation in saying that no amount of mere sugar feeding will cause brood to be reared unless natural pollen is being gathered at the time. Thus in fact are our valuable queens being overtaxed for nought. Yet how naturally the bees will, without any such stimulant, start brood-rearing even in midwinter! Why? Because by that time they have consumed so much of their honey that the buried pollen is once more discovered, to be applied in the most natural way to the rearing of their young.

As the result, then, of the past season's experience I would pro-

As the result, then, of the past season's experience I would propose the following rule as to feeding—viz., when brood-rearing is no object feed as rapidly as possible, otherwise feed very slowly, and make sure either that there is considerable stored pollen in an unsealed state, or that it is being gathered at the time, or supplied in an artificial form.—WILLIAM RAITT.

CHAFF COVERS.

FROST has now given us a decided grip, and but little supplementary work can be done in the way of defending bees from its rigour. If winter passages have not been made our stocks must take their chance without them. If our hives have not been contracted the poor bees must fight as best they can against the excessively chilling effect of an unnecessarily large number of combs and extent of hive wall, until some considerable rise in combs and extent of hive wall, until some considerable rise in temperature makes it possible to remove the excess, putting in a dummy or false hive side and filling-in the spaces made with chaff, hay, fine shavings, sawdust, rags from the ragbag, cotton waste, cork dust, or some such non-conductor of heat. Of all these I prefer the first as most handy and economical, while for wintering even strong stocks would recommend not more than seven Woodeven strong stocks would recommend not more than seven Wood-bury frames or their equivalent. I have several lots far from weak to which only five frames are given. These, of course, need to be well stored with honey while the bees—filling fairly the whole space allowed them, and clustering safely even against the well-defended hive side—are snug and dry in every part. No combs are mildewed, and when spring with its strengthening sun again results, now, as the removed combs can by degrees be added to

smiles upon us the removed combs can by degrees be added, to the immense advantage of the then strengthening colony. But one method of increasing the protection of our stocks in frama hives the present cold will not prevent us from adopting. I allude to chaff covers. The greater number of bee-keepers are now using quilts over the tops of the frames; but if instead of the divided crown board, or even the now almost obsolete single crown board be retained, the chaff cover will be found equally valuable. the consists simply of a frame of thin wood nailed together like the four sides of a shallow box, about 8 inches deep and of the length and breadth of the hive or portion of the hive containing the bees. To the edges of this wood, so as to form the bottom of the box, is fixed with tacks a piece of cheese cloth sacking or felt (I usually use the scrum which has through service become untrustworthy for confining swarms), and then the cover is placed over the quilt or comming swans), and then the cover is placed over the quit of crown board as the case may be. It is now filled up with chaff, when, without impeding ventilation, it protects in a most effective manner from cold. The quilt in such weather as we are now experiencing will always feel very chilly to the hand; but if a chaff cover be used and it be lifted the quilt beneath will appear warm to the touch, a proof at once of the conserving power of the chaff. We shall appreciate the value of the chaff cover if we remember that it is above and at the upper part of the hive that protection is of most service—a fact forgotten apparently by some, since prize-winning hives in a few cases have here been the thin-Where it is adopted the bees will be found less impoverished in stores, stronger in numbers, and individually more vigorous in the spring than where excessive leaking away of temperature has been allowed.—F. CHESHIRE.

NEW HORIZONTAL OCTAGON HIVE.—Would "ALROFI" please to give the particulars he promised in his article, 12th of June, about Mr. Paterson's hive? Is it square or octagonal? If the latter, how does he get across to the frames? Does he use wax sheets? Is it 14 inches in length and breadth? How does he siper it?—Prestwick.

OUR LETTER BOX.

FOWLS DYING $(F.\ A.\ B.)$.—Your fowls are dying of liver disease. It arises probably from feeding—for instance, the potato as the principal

article of food almost always causes it. Maise given in undue quantities will produce it. All the deviations from natural food have a tendency to cause disease. In poultry it is almost always the liver that is attacked. Feel them morning and evening on barleymeal or ground oats laked with water. Give them at mid-day some maize or kitchen scraps. If they have no access to grass or green food supply them with sods of grass or lettuce or other green food; cabbage is the least useful of all vegetables for this purpose. In such cases as yours the diet of the birds should be mentioned when information is requested. mation is requested.

COCK'S COMB PECKED (M. B.).—So long as the bird is allowed to remain with the heas they will pick his comb, even until they pick a hole through it. They are tempted by the raw and bleeding wound, and the cock submits. Remove him, dress the wound with citron ointment; it will soon heal. He must not be put with the heas till it is quite healed. While the severe weather lasts he should be somewhat protected from it in a loose box, barn,

MARKING POULTRY (N. E.).—Much depends on whether you wish to mark fowls in a manner known only to yourself, or so plainly as to make them distinguished easily when running in a yard for kitchen purposes. If the latter, there is no better plan than a ring of wire round the leg; and as it is no inconvenience to the wearer, different broods may be marked with one, two, and three rings. Another mode is by sewing cloth or list round the leg. Different colours denote different broods. Private marks may be made in the web of the wing; others cut out small notches in the beak and sometimes in the eyelid.

PROFITABLE POULTRY (Inquirer).—We shall shortly publish notes on this subject, which you may read with advantage.

EGGS SMALL (F. D. S.).—The eggs that you regard as small are probably the result of the "mixture of breeds," especially as two out of three varieties of fowls you name do not lay eggs that are considered large. Spanish usually produce fine eggs. The food you give is right; give as much as the birds est freely, but not more.

COMBS FALLING (Reader).—Hives without cross sticks are easily injured in moving them, and very often the combs fall and smother the bees. No one without seeing the skep can advise you what course to pursue. If the breakage is not serious it will perhaps not be advisable to do more than remove any shattered fragments; if the injury is great we fear you can do but little to rectify it. You must rely on your own judgment and ingenuity in finding the best remedy under the circumstances.

From observations taken near London during forty-three years, the average day temperature of the week is 46.9°; and its night experature 34.4°.

WOODLAND RIDES.

REALLY must write something for the Journal," I said one morning to the partner of my sorrows: "but what to write about I do not know." "Oh, there is plenty to write about. Set to work." "What?" I asked. "Well, there is the Rose." "Every conceivable subject bearing upon the Rose has

been written upon usque ad nauseam—exhausted, in fact." "Well, there is the Gladioli. You have grown some beauties; even now at the end of November they are grand." "But I have already written all I know about them." "Oh, then (with triumphant voice), there are the woods! write about your improvements in the woods." So I am fain to ask you, Messrs. Editors to accept the following as an apology for an article, and if you blame me-well; perhaps you, too, are married. I say

At a time like this, when there are so few flowers, and those that still remain with us are so dull and uninteresting; when the leaves are falling all over the lawn, when all around are signs of decay and death, when "chill and dim falls on the moor the brief November day;"-at such a season as this it is exceedingly pleasant to have a walk

along the well-kept rides of a wood.

I have for the last two years been making improvements in a very large wood near here, and with the consent of the owner been making new rides, and I have derived more pleasure from doing this than spending money on Roses that will not grow, or fighting with the miserably poor soil that abounds in this neighbourhood. "A congenial and an appropriate occupation," some of your readers may say; "for where better can a Wyld Savage be than among his native wilds?" This may be so, and I do not deny that it is, but at the same time I think that men who are not savages may derive a great deal of gratification from walks and rambles in large woods even in the winter time. Winter has its advantages here, too, as elsewhere. There are no snakes, and those venomous reptiles, adders or vipers, which abound here have retired into winter quarters. It is dangerous to allow young children to walk in the spring and summer in the woods or scramble up the banks where those adders are

Here in this hilly country the vistas and views to be seen in the woods are so numerous and so diversified that lovers of Nature are delighted to see them; and I only wish I had the privilege of showing some artist a few of the views. The great drawback to a ramble in the woods is the wet. Most woods hereabout are full of springs, and as no landlord thinks it worth while draining them, the rides are nothing but swamps. The sportsmen, on the solitary occasion during the year that they visit the woods, are prepared for any amount of swamps, and dress accordingly; but for ladies or children, or even for men to walk therein, it is exceedingly unpleasant. The first thing, then, is to drain them. At first I tried what might be called spot draining

water from the higher ground used to filter through on to my rides, and so I was compelled to change my tactics. I now make a long open drain the whole length of the ride the side nearest the bank, and the water which before was a great nuisance now becomes an object of beauty. For, as in some fertile soils, we are told that you need only tickle the earth with a rake ere it laughs and sings-that is, bears corn, so here wherever you dig out a trench or a drain up there springs almost by magic every kind of Moss and Fern and Lichen, so that as you walk along the rides you see the water dancing in the fitful sunlight, and the Ferns gleaming with the dewdrops. To keep a ride in good order it is necessary for the sun and the wind to be able to enter in on one side: and here there is a difficulty, for most rides are lined with Holly, Firs, and Birch, and the majority of landowners have an insuperable objection to any of these trees being cut or pruned, so that the sun can only struggle in a few places, and the surface of the ride is always more or less wet except in the very driest weather.

The perfection of a ride is one where the foliage is dense on the north or east side, but open to the sun on the south or west. You then look down, when the wood is hilly, upon the trees lying at your feet and on those at the other side. Our wood is in the form of an immense horseshoe, the outer rings of the shoe all being on high ground. The rides are on each side of the rings and one through the middle, which is the worst to drain. But when the water is taken off the rides it soaks away in the porous soil and is no more seen for a time; but like the subterranean Nile, as soon as we cut a new ride we find water bubbling up from the ground, and we know that the water of our rides has found an outlet at last. The water then gradually reaches the bottom of the wood, where it forms a small stream, which is one of the sources of the river that runs into the sea at Charmouth. And here the lover of woodland walks can make a very pretty use of it; for with a very little trouble and expense he can make a small pond or miniature lake, in which he may grow Water Lilies, Water Hawthorns, and other aquatics. I am told that Mr. G. F. Wilson has devoted a large wood to the cultivation of his favourite flower the Lily. I wonder if his neighbours think him as mad as my parishioners think me-all, that is, except the man who is employed therein. I can sympathise very warmly with Mr. Wilson, and hope he will do the same for one is always glad of a sympathising friend. But I doubt where in a modern garden more lovely spots can be pointed out than in some woods. I could show you a place here where there is a sort of ravine for about 30 or 40 yards amid which all sorts of Ferns are luxuriating, and this ravine is hemmed in by Hollies and other bushy trees, forming the most sheltered spot imaginable. Then, again, a wood like ours, at least is such a sheltered spot, you may go out on a cold day with the north wind almost blowing your ears off, and as soon as you get into the wood you do not feel it; you appear to be in another climate. As my old woodman says, "It seems somehow to blow over the wood and not reach you." Then there are the glorious tints at all times —that is, making a short spur from the spring to the other side of the bank, but I found that after every storm the one say as they read this, "At all times of the year! Are of the year to delight the eye, which I fancy I hear some NO. 1628.-VOL. LXII., OLD SERIES.

NO. 976-VOL. XXXVIL, NEW SERIES

there any tints in winter?" "Yes," I reply, "most decidedly." the Birch trees have a tint or shade of colour in their bark and in their branches which quite gives a silvery gleam to the landscape in the winter. Then there are the common Holles with their very dark green foliage, and with their charming scarlet berries; and the Hazels, which have a tint quite peculiar to themselves; and the Oaks with their stalwart limbs encased in Ivy. There are many and varied tints even in winter. And then how delightful to walk in the woods and to notice the first, the very earliest, signs of the awakening of Nature from her long winter slumber which are to be seen in the woods!

Long before the garden shows signs of spring the woods do; not perhaps apparent to every careless eye, but the earnest lover of Nature notices signs that tell him the tide has turned, the long lane is nearly ended now, and soon we shall have spring. Then the lover of natural history will find the woods an endless source of delight. How Thomas Edwards, the great naturalist and shoemaker of Banff, would rejoice in such a wood as ours! Stay here a moment behind this tree as the evening is drawing nigh, and the rabbits will one by one steal out of their thick cover and begin to play with one another like a lot of children over the nursery fire, while overhead the wood pigeons will coo away for a time one of the softest and most musical songs that I ever heard. But, alas it should be so! After a time two will begin to fight, and don't they just go it when they begin! and whilst you move to look at them the very least sound made will set the whole flock of these extremely shy birds in motion, and with loud flapping of wings and with a noise like a whirlwind they will scurry away to a distant part. Then as you walk on you hear the strange sad cry of a rabbit in pain. You go quickly and quietly on, and there you see a poor bunny in frenzied agony running round in a hopeless attempt to get away from a skunk or a wessel. Then overhead, jumping lightly from tree to tree as cleverly and lightly as a flyfisher whips a stream, comes a nimble squirrel with its chestnut brush and bright eyes looking for acorns or nuts. It is a most interesting sight to watch how cleverly he moves along the branches. He will bear his weight to the very last inch before he makes his spring. There is a tradition here that about fifty years ago a squirrel could go from here to Chard, a distance of ten miles, without touching the ground.

Next it is so easy to improve the rides at very slight expense by planting at the margins robust or free-growing plants. There are numbers of herbaceous plants that grow and spread so rapidly that they soon take up far more room than we can afford to give them. Herbaceous Asters or Michaelmas Daisies, for instance, soon spread over much ground, and Potentillas when once established spread exactly like Strawberry plants. Fuchsias here, too, grow into huge bushes—almost, indeed, attain to the proportions of trees: what is easier, then, than to transplant some of these to the woodland rides? Old and exhausted bulbs, too, may be planted here, although the field mice make great havoc among such as the Crocus and Scilla; and above all other plants or trees the Rhododendron, the most charming shrub, may well find a home in our woods. In fact it is more suitable for woods than any other place. It makes a beautiful cover for game; usually rabbits will not attack it, and the flowers in spring and early summer make the most delightful progreet.

Then if expense need not be considered, or a certain sum is devoted yearly to the improvement of the woodland rides, what a splendid pinctum could be formed in some open space! I hope in future years, if I stay here, to make what I shall call a Cedar ride—for of course all the rides are named—which shall consist of a ride bordered by all the best Pines and Conifers. When that is done and a few years have clapsed I fancy my successor. or even perhaps the noble owner, will bless the name of—WYLD SAVAGE.

THE ROOT-PRUNING OF FRUIT TREES.

OF all operations connected with fruit culture that of rootpruning is perhaps the most important, although there are few places where it receives anything like the attention or skill that is generally brought to bear on other branches of gardening. This work should be scientifically and carefully conducted, but instead of that it is frequently entrusted to rough inexperienced hands, whose knowledge of the purposes of the different kinds of roots and the functions they serve are of the most imperfect character. Such men as these cut away with spade right and left all that comes in the way, and at equal lengths big or little feeders; therefore it is not surprising that results have been anything but satisfactory to those who have had the work carried out in the manner described.

After close observation we have found that where a coarse strong shoot is produced in a tree there will be found a gross fibreless kind of root, either as a tap going straight down, drawing the supply of sap from cold wet soil or other source where the conditions are not favourable; therefore, if we wish to restore an equilibrium of growth and bring about fertility the right way is to assail all such roots wherever they may be situated and shorten them back considerably, in order to force them to throw out a network of small fibres to feed nearer the surface. In wet stiff land even a disturbance of the soil often effects much good, especially if a few barrowloads are taken out and replaced with some fresh turfy loam and road scrapings; indeed, in all cases of root-pruning this is advisable, as it is astonishing what a little assistance given in this way works in bringing them round to more fruitful habits.

The difficulty, however, with some growers is not how to

The difficulty, however, with some growers is not how to check these trees from making coarse strong shoots, but, on the other hand, how to get sufficient growth and strength to enable the trees to carry good crops of fruit, and particularly so is this the case with Pears on the Quince stock trained as pyramids, which in light dry soils nearly always present a starved appearance, and seldom ripen fruit fit for eating. Although the Quince is a moisture-loving tree we not unfrequently see Pears worked on it planted on raised mounds, which, unless on very heavy retentive lands, is the worst practice possible. Better far, instead of doing this, is to allow the collars of the trees to be even alightly lower than the general ground level, that water or sewage can be easily administered during dry weather without loss.

On light dry lands the Pears are often checked from want of moisture just at the time they ought to be swelling freely, and the skin in consequence becomes contracted, and the flesh hard and gritty, so when rain comes the greater portion of the fruits crack and are of no further use; a few of ours used to be in this unsatisfactory condition, but since we have added a quantity of clay to the soil they bear abundantly, and are in quality everything we can desire. Those, therefore, who are troubled in the same way cannot do better if they have light land to deal with than to set to work and improve it in the same manner; although it entails considerable labour, it amply repays it in a few years. The way we managed so as to raise the general level was to wheel out as work progressed about 8 or 10 inches of the sandy subsoil, and in trenching the same quantity of clay was brought back to replace it, and trenched in 2 feet from the surface, where the principal roots are buried; in this way it parts with its moisture slowly, and always contains a good supply for the tree to feed on. In trenching the trees were not unduly disturbed, but allowed to stand on a solid base of earth about a yard through, thus preventing them from receiving a severe check.—JOHN LLOYD JONES.

ISOLEPIS GRACILIS.

I WISH to make an appeal on behalf of this well-known decorative plant. When I first made its acquaintance it was as a stove plant, but some years ago I tried it in the conservatory with good results. After coming here I raised a stock of plants from seed, and now employ it regularly as an edging to the other plants on the side stages of the conservatory. The plants are grown in 3-inch pots in good rich soil, and supplied constantly with liquid manure. This is necessary in order to keep the plants growing freely and the foliage of a healthy green colour. Sometimes we place the pots in small sancers full of water. This is particularly necessary when the plants are used for furnishing tables in rooms, as they become dried up very quickly in such positions, a certain result being yellow foliage in a few days. In spring the stock is divided into small pieces and potted. Placed in a vinery for a few weeks they soon become established. They are then repotted in 3-inch pots as at first mentioned, and when of a size to be of value in a decorative sense are placed round the stages of the conservatory. When well grown the Isolepis is equal to any other green-foliaged plant in cultivation.

In making the arrangements for the planting of the flower garden last year it was placed in a prominent position as a dividing line. What may be of interest to many is that these plants are still alive, notwithstanding the continued frosts we have experienced. In Paxton's "Botanical Dictionary" there

is an Isolepis nodosa from New Holland with "gracilis" as a synonym, also an I. gracilis without references. Which is the one under discussion, and where was the latter imported from?

—R. P. BROTHERSTON.

PEACHES ON OPEN WALLS.

PROBABLY some of those who aspire to the cultivation of Peaches on open walls would feel somewhat discouraged on reading the remarks of "ESSEX" on page 401 of the Journal. Your correspondent infers that further north than London securing crops of Peaches on walls is a matter of chance; and that the expense incurred by keeping the trees clean would go far towards covering them with glass, when it is presumed they would not afterwards be infested with aphides or other pests. It has been my experience to note that plants subject to aphides and other insects are much more infested when coddled under glass than in the open air.

Although I have to contend with the cold climate of Rox-

Although I have to contend with the cold climate of Roxburghshire, as far north as the Tweed, yet I have had good crops of Peaches on walls during the last ten seasons, and the trees now promise well for future bearing. My wall is 14 feet high, 130 feet of the southern aspect being covered with Peach trees, the other portion being devoted to Apricots; and although I lost many valuable shrubs and ornamental trees last winter, only a few small dead branches here and there on the Peach trees indicated the severe frost to which they were exposed. The Boyal George and Noblesse are the two varieties which succeed best with me. In spring, after being pruned they are syringed several times with black soap and flowers of sulphur diluted in hot water. This destroys the eggs of green fly, &c., located in the bark, and especially in the nail holes and crevices of the wall. A dressing at this period tends to keep the trees clean all the season; it is of little use syringing when the leaves are all curled up and unsightly. This must be prevented, and success will be the result.

Eventually the critical time arrives when the blossoms must be protected, to save which many methods have been devised. Some approve of permanent glass copings, which, I think, often keep the soil too dry at the base of the wall where many of the roots are; others approve of spruce branches stuck in. The latter method of protection I have practised, likewise hexagon netting; both, however, with indifferent success. About ten years ago I gave Frigi Domo a trial, and found it proof against all spring frosts, and shall continue using it until a better canvas be produced. I fasten it to a round piece of wood along the face of the coping, and keep it free from the trees by means of stakes placed 3 feet apart, the upper ends beneath and pressing firmly against the coping, while the under ends are let into the ground. This screen is drawn up every morning, except when stormy, and drawn down every night, and fastened at the bottom by means of pegs pushed into the ground. This secures me a crop with certainty every season.—ROXBURGHSHIRE GARDENER.

WINTER FLOWERS.

WE seem to have plunged suddenly into the very depth of a bitterly cold winter. The cold to-day is quite equal to anything we had last winter, and we are only at the beginning of December. It is bleak and dreary outside in the garden, but within the vinery so bright and cheery and warm that it is like stepping suddenly from winter into summer; a delicious fragrance, too, fills the air, for there is a row of Roman Hyacinths in full flower. Those plants which give us flowers in November and December are especially precious. Chrysanthemums are our chief resource, and I have been more than ever pleased this year with some noble specimens of Elaine, James Salter, and Fair Maid of Guernsey; but to make a house of any size look gay you must have small as well as large plants, and except under very careful treatment Chrysanthemums are apt to become "leggy."

I know of no plant so pure and sweet as the Roman Hyacinth, unless it be another bulb, the Paper White Narcissus. But this latter is not nearly so free-flowering as the Hyacinth. Out of a hundred of the Roman Hyacinths I have only one which is doubtful about not flowering, and nearly all send up two spikes; but out of a dozen of the Narcissus more than half will fail. This is provoking. I should be glad to know whether others experience the same thing. I cannot think that it is the treatment, as they have been brought on care-

fully—first of all in a warm dark cellar, and then, when the pots were full of roots, in a greenhouse, where the forcing was very gentle. I have given them saucers since they have come to the upper air, but all is no good, and my experience this year only confirms what I have had to put up with in former years; so much so that I have sometimes said to myself, "I will buy no more Narcissus," but the thought of the exquisite scent and the long duration of the flower has after all induced me to change my mind. The double Roman Narcissus has behaved unusually well with me this year in the matter of flowering. Nearly every bulb is throwing up a spike. It has had exactly the same treatment as the Paper White, but is some weeks in advance of it. The fragrance is delicious, but the flower itself, like a great many other double flowers, is wanting in grace and beauty. If you wish to secure an abundance of sweet white flowers in November and December obtain the Roman Hyacinth. If you have a good temper and can stand disappointment for the sake of an exquisite fragrance which will last a long time have the Double Roman, or the Paper White Narcissus.

I have never succeeded so well with the Richardia as this year. I attribute it partly to the wet summer, for one of the difficulties I meet with in the factotum who manages my garden is to get him to water it enough in the summer. The plants of Richardia were planted out in the kitchen garden, and then produced so many of their large white spathes that I half sighed as I gathered them to think that in the winter they would be exhausted, and we should have no more; but it has not been so. They have been ranged in large pots on a back shelf in the vinery, and there they have continued producing their spathes, and I feel confident I shall have plenty for Christmas church decoration. In the controversy, therefore, about what is the best to do with your Richardias in summer, I decidedly give my vote in favour of the planting-out, but I fancy in most seasons a trench would be of great service in keeping sufficient water about the roots; moreover, I do not think that the situation should be a warm one, but only half exposed to the sun. One very great advantage of the Richardia is that the spathes last so long in the room. In these days of room decoration, when large stately growing plants are so useful for that purpose, few are more welcome than the Richardia. At this time of the year to have the dark glossy leaves and tongue-shaped spathes ornamenting some bright corner in the drawing-room is indeed gratifying.

Double Primulas are also early winter flowers almost invaluable. The double fringed are nearly as pretty as single flowers, with the great advantage of standing so well after being cut. The old Double White seems to be more floriferous than the large and beautifully fringed specimens of more recent days. But the latter make up for quantity by the richness and fulness of a single truss. I find that they like deep potting, and that they are less likely to damp-off when so treated than when the rootstock is above ground, and the plant consequently unsteady. With a very little care they can be made to flower during the whole winter. Two words, I should say, give the chief requisites for successful cultivation—viz., warmth and air. Cyclamens require much less of the latter; in fact, I never succeeded so well with any as with some which I shut up in a cold frame in early spring and kept close during the hottest days of April. They came on quickly and flowered, as Cyclamens will flower when well treated, till they became a mass of starry blossoms. But they are sulky, and the special aversion of my factotum, who declares he can make nothing of them. He begged me to buy a packet of seed a few years ago, because he thought he could do better with younger corms. But it was only the same thing again. I have taken them in hand myself now, and I hope to have Cyclamens again this winter. I am sure that one great secret is to give them proper treatment in summer, and I believe that treatment is to plant them out in a sunny position and to give abundance of water.

I must not forget to mention as a first-rate plant for this season Abutilon Boule de Neige. It flowers freely, is easily grown, and has good foliage. The only quality about it at all objectionable is that it does not seem to like a visit to the drawing-room. It is essentially a conservatory plant. Perhaps some would find fault with it for not having any scent; but the globe-shaped bells are lovely enough to do without that. Give this Abutilon plenty of water and good heat and you will have abundance of flowers. A few days ago the border between the white cloth outside and the satin centre of a large dinner table was composed of flowers of Luculia gratissima. This made

a lovely border, and the scent was quite delicious. It is an old-fashioned plant, but that only makes it the more valuable.—A GLOUCESTERSHIRE PARSON.

SLUGS AND SNAILS-HOW TO DESTROY THEM.

A FEW months ago I started the above inquiry, and having tried all the various means recommended in your Journal, I have come to the conclusion that common salt properly applied is not only the cheapest but most efficacious remedy against the slugs and snails, and at the same time beneficial to the crops. I pay 1s. 6d. per cwt. including delivery for dirty common salt; it can be bought for £1 per ton for a railway truckload. I had it sprinkled over the surface of my garden like a shower of hail. The result was that next morning hundreds, or rather thousands, of snails and slugs were lying dead. The dressing was repeated the first moist day about a fortnight after, and again after an interval as soon as the enemy showed in force. I have also had my manure heaps dressed liberally with the salt, for, as my man-of-all-work says, "the slugs can't get through it as they did that nitrate," alluding to the fact that the big white and also black slugs on being dusted with nitrate appeared to throw off a slimy overcoat and to glide away unhurt if a second dusting of nitrate was not promptly administered; whereas the common salt appears to adhere and ultimately to kill them—as my man says, "they cannot get through it. Of course the salt, like many other good things, must be used, not abused, or damage will be done to tender plants.-G. O. S.

OUR CHRISTMAS VEGETABLES.

Considering the severe winter we had last year, followed by the backward spring, ungenial summer, and early and severe winter of this year. I fear that with many an abundance of superior vegetables will not be easily secured. Outside vegetables are far from being so hardy or well developed as they were last season at this time, and should the weather continue as frosty and cold as it is at present vegetables will be far more scarce in the spring of 1880 than they were in 1879. Does someone say, "Well, this must be the fault of our gardener?" Decidedly not; weather influences, especially on outside crops, cannot be effectually avoided. The supply of vegetables in winter or spring can, however, be increased by forcing. In some gardens with abundance of heated glass houses, pits, and frames many vegetables may be had, certainly not without expense, but with little trouble or skill.

In the first place no garden of any pretensions should be without a good supply of stored Carrots, Beet, Parsnips, Salsafy, Onions, Turnips, and other roots for winter use. These all may be and should be grown in summer and autumn and stored away ready for use, and their supply should cause no gardener anxiety at Christmas. We next come to the green crops. In the open air Brussels Sprouts must always be regarded as one of our most valuable vegetables at Christmas. It bears severe weather better than any other, and the sprouts can always be used whether they are large or small.

Broccoli cannot be so favourably spoken of, as it is so much influenced by the weather. Plants which might give promise in October of being ready for use at Christmas may not come in until February. No variety that I am acquainted with will make much progress during severe frost or snow, and those which may be forming heads, say about the beginning of December, may be injured before Christmas unless they are carefully protected. It is in this respect they differ so much from Brussels Sprouts. Our Broccoli for use this year at Christmas consists only of one variety—viz., Veitch's Autumn Protecting. Many of the plants were forming heads rapidly during the latter part of November; some of these have had all the leaves tied over them, others are cut and stored, so that altogether we are fairly well off for Broccoli.

Savoys are plentiful, and so are Cabbage sprouts and Coleworts. Curied greens will not be touched until the weather has destroyed all else, and well-blanched Leeks may be used occasionally to save other vegetables. Last Christmas we had abundance of well-blanched Celery, but owing to its being so highly earthed up much of it decayed shortly after that time. Now we have plenty of it, but not so much earthed, and we hope to find the benefit of this in spring. Lettuces are best under frames. Radishes are sown in boxes placed in vineries; Mustard and Cress is treated in the same way.

Tomatoes were not a profitable crop out of doors this season;

we did not gather a ripe fruit from one of our outside plants. Our Christmas Tomatoes are those gathered green from plants out of doors and hung up in bunches in a Pine house to ripen. They would ripen equally well in a room; and those with no glass houses, but who like Tomatoes, might grow their plants and green fruit against any open wall in summer, and have them ripe in their rooms by Christmas. Unless with those persons very advantageously situated French Beans cannot be had in large quantities at Christmas. We generally gather a few until that time from plants in pots or boxes. Damp and a low temperature are very injurious to them when they are in bloom.

Asparagus is one of our favourite Christmas vegetables, and this season we have it both green and white. For flavour the first must be given the preference, but for tenderness the latter is liked most. The green is being cut from a bed in a Cucumber pit where a bottom heat of from 40° by night to 60° by day is maintained. The white or blanched form is growing in the Mushroom house where the atmospheric temperature is always about 55°, and bottom heat is supplied from a mixture of dung and leaves. In this way I am sure Asparagus might be had anywhere by Christmas in a cellar. Roots from four to twelve years old are not difficult to start into growth. In the same house Mushrooms are pushing up thickly from beds composed chiefly of leaves, and those who think they cannot have Mushrooms at Christmas without horse droppings might try a bed made up about the end of next October with any kind of leaves, and a sprinkling of littery horse or cow dung to raise a heat.

Seakale and Rhubarb treated the same as the white Asparagus are soft and tender, and both are most useful when either fruit or vegetables are scarce. Herbs dried and forced, besides Parsley, which is always in demand, are easily secured, and the supply from the kitchen garden at Christmas cannot be complete without them.—A KITCHEN GARDENER.

GRAPES RIPENED WITHOUT FIRE HEAT.

A FRIEND of mine, a retired brother of the craft, has built three vineries in Devonshire to keep himself engaged, and also hoping they would turn out to be profitable. The first house was built three years ago this autumn, the Vines planted at once; since then they have done well. The varieties planted were Black Hamburgh, Black Alicante, Gros Colman, Lady Downe's, Madresfield Court, and Waltham Cross. The Black Hamburghs bore twelve bunches each, well coloured, and about four on each Vine weighed 3 lbs. each, the others from 1 to 2½ lbs. The Gros Colman averaged ten bunches each, the largest weighing 3½ lbs., the others in proportion, the berries being good and well coloured. The Lady Downe's Vine bore eighteen bunches averaging 1 lb. each. well coloured, berries very fine. Madresfield Court, fine large bunches, well coloured, but every berry cracked. Waltham Cross did not set a single berry, was therefore of no use. The Black Alicante did not set well, but the bunches were large and well coloured. Commenced to cut the Hamburghs the 1st of September, finished cutting the Gros Colman the first week in November. This house has had no heat since it was erected, nor is there provision made for any. The other two houses are just finished they are span-roofs, the other a wide lean-to.—Ebombona.

SEED POTATOES.

SEEING so many "cautions" in the papers about seed of the Magnum Bonum and Champion Potatoes I beg, for the good of that section of the public who have not had experience on the subject, to offer a "few" suggestions. Each year now it is quietly suggested by a caution that the public are only safe in obtaining their seed of some particular merchant in the trade, who each year gives out that he and his firm bought the whole of the crop of Mr. So-and-so's Potato. The unthinking public swallow this, to my mind, very tasteless bait, forgetting that if a good Potato is really well and honestly proved to be a resister against the disease in one season it will have become the property of a very large number of the community, and that the seed can be had quite true, pure, and good from any one of the growers who annually sell in their districts. If a man is ignorant of the varietics of Potatoes and has not the chances I name near home he must go, of course, to one of the respectable large firms. I maintain the prices given last year, for Magnum Bonum Potatoes were needlessly high from the large quantity that were in England; and though they and the Champion are now so plentifully grown and have succeeded

so well in most places, it is evidently sought to make it be believed that seed of these two varieties will be both scarce and dear. I purchased some seed of Magnum Bonum last year from two of the great firms, also some from a third party. prove my assertion 1 will place six Potatoes from each lot, and challenge the most experienced of the three vendors they came from to pick out their respective lots. All were grown on the same ground, all perfectly free from disease—not one bad tuber in an immense crop. I am a buyer again this year to send to my tenants in Ireland, but I know numbers of people in England and Scotland who can produce quite as true and good seed as need be planted.

I take it in this particular case it is the duty of all persons to try and scatter widely in these depressed times a Potato that has proved to be disease-resisting, not to try and keep up the price and prevent those from obtaining it who cannot afford fancy prices. In this particular season, and after such a bad time for agriculturists and horticulturists, I say the man who will sell any good seed at a fair price ought to be dealt with.

I write this partly hoping it will induce persons having more seed of Magnum Bouum, Champion, and Alpha Potatoes than they require to advertise them. They need not fear but they will get a ready sale at remunerative prices, and lend a hand to assist the small holders of land, cottagers, small Irish and Scotch tenant farmers, and labourers who require a change of Potato seed more than most large occupiers of any rank. These are exceptionable times and have been very bad during the last two years, and I think all should lend a helping hand to prevent further distress to thousands of struggling cultivators.-A LARGE POTATO GROWER SINCE 1846.

[We learn that Messrs. Sutton & Sons of Reading, and Messrs. Carter & Co. of High Holborn, London, have granted, free of charge, to the "Irish Farmers' Gazette fund" Potatoes of the Scotch Champion and Magnum Bonum varieties, amounting in the aggregate to upwards of six tons, for free distri-bution. These firms are also supplying those varieties at reduced rates when purchased in large quantities by landlords for sending to their tenants in Ireland.—EDS.]

THE DUNMORE PEAR.

SOME time since I bought a piece of ground on which a gardener, now deceased but once well known in this neigh-bourhood, had planted a Dunmore Pear tree. It is now a lofty large-grown standard, and every year produces a crop of dark brown full-sized fruits. This year the crop has not only been large in quantity but also excellent in quality; so excellent, indeed, that out of a large selection my household unbesitatingly give the palm to Dunmore. Some, indeed, of my friends declare that they have never tasted Pears equally good.

My friend Mr. Tranter, the gardener to the Hon. Granville D.

Ryder, at Westbrook Hey, near Hemel Hempstead, who cultivates more than fifty varieties, endorses my opinion of this Pear, and tells me that it used to be a great favourite in Scotland. The Pear, perhaps, is named from a village on the Firth of Forth, close to which is Dunmore Park, the seat of the Earl of Dunmore. In spite of its excellencies the tree is evidently not much known. I cannot find its name in Messrs. Veitch's catalogue, though almost every new variety of Pear is mentioned In Messrs. Lane's list it is described as a good bearer as a standard, fine, melting, a table Pear, first-rate in quality and size. With me it usually ripens in October and November. -E. BARTRUM, Berkhampstead, Herts.

[The Dunmore Pear was one of Mr. T. A. Knight's seedlings, and was named after Dunmore in Stirlingshire.—EDS.]

HEATING BY PARAFFIN STOVES.

1 AM of opinion that paraffin stoves, if rightly made and properly managed, are capable of preserving bedding plants from frost. When these stoves are employed it is not because they are selected as the best of heating mediums, but rather as the only stoves that can be obtained by small owners yet great lovers of plants. Such possessors of miniature green-houses are in this position—without some artificial heat their plants will inevitably be killed, but with the aid of the stoves a portion may be kept alive. The stoves, then, are not selected because of their intrinsic superiority as generators of healthy heat, but are rather adopted on the principle that when two evils exist it is prudent to choose the least.

object that perhaps nine-tenths of those who employ them have in view. The most important of bedding plants are Geraniums, and these probably constitute 90 per cent. of the plants that amateurs desire to preserve. Geraniums, then, I do not hesitate saying, may be kept alive and in a fair degree healthy by the aid of the stoves in question. My authority for saying this is that I have during previous winters successfully preserved my little stock of those plants by the aid of a paraffin stove.

If I am asked for the very best mode of managing bedding Geraniums in the winter my reply is—Have strong sturdy plants in single pots, thinly placed in a light position, and kept in a steady growing state in a temperature of from 40° to 45°. That, however, is a practice that can only be indulged in by the few who have houses or pits of the most approved

construction heated by hot water.

In the case of the many whose only means of excluding frost from their Geraniums is by the aid of paraffin stoves, a totally different system of practice than that alluded to must be adopted. Instead of any attempt being made to produce a temperature sufficiently warm to keep the plants growing, the plants must be kept as much as possible in a state of rest, and should not be awakened from that rest by artificial heat. It is only by acting strictly on that principle that success can be expected. I cannot, perhaps, more usefully convey information on the subject in question than by describing the condition of on the subject in question than by describing the condition of my own plants and my mode of procedure in preserving them. Some of the plants are old, having been taken up from the beds and potted; others are young, the cattings having been struck in September. Some of the plants had been cut down three weeks previously to being taken up, and were potted just as they were making fresh growth. These are very dwarf, and will make useful bushy "stuff" by next May. Others were not cut down, but were potted with their growths intact, except the removal of an occasional straggling shoot for symmetry's sake. But, although the plants were not pruned, all the leaves were removed at the time of potting except a few at the tips-small leaves not much larger than a shilling. Evaporation of the juices of the plants was thus arrested by the removal of the evaporating surfaces, and at the same time the stems were exposed to light and air and became firm and solidified. Until October the soil was kept moist to incite a little root-action, but on the approach of damp and cold weather the water supply was gradually diminished. The same general treatment was adopted in the case of the cuttings, now young plants; and the whole stock is hardy and healthy, but—and this is important—at rest.

In this state the plants will endure two or three degrees of frost without being injured, but if they had been kept growing half that amount of frost would ruin them. All that my plants require is to have the temperature a few degrees above the freezing point. I never light the lamp until the thermometer in my greenhouse stands at 35°, and then not for the purpose of raising the mercury but to prevent it falling below the point named. Were I to raise the temperature of the house 10° I should do more harm than good to the plants, besides wasting paraffin. That is where mistakes are made in stoveheating—firing to raise the heat instead of just to keep our frost. Last winter I preserved three hundred plants. I have firing to raise the heat instead of just to keep out other plants in my greenhouse besides Geraniums-Ferns and Heaths, the latter in flower; Echeveria retusa, also in flower; Palms and green Dracenas, and none of them have received any injury during the severe frost.

A word about the stove itself. It is one of Rippingille's, and has a large free burner, the flame being protected by a large open shield. This is important, and equally so that the perforated plate below the burner be kept clean, because then the requisite supply of oxygen is provided to secure a clear flame devoid of smell. With a contracted shield the flame, unless put "full on," which is seldom necessary for long together, is dull, and the effluvium therefrom is unpleasant and injurious. In a word, the lamp is used, not abused, and it answers its purpose well. Where injury results in heating by paraffin it is either the effect of attempting too much, or of bad paraffin. I only use the best.-S. W.

THUNBERGIA HARRISH.—Is not this the queen of stove climbers in winter, with its bold pendant clusters of pale blue Gloxinia-like flowers, which come in such abundance as to form "a cloud of bloom?" The foliage, too—long, elegant, I have stated that paraffin stoves are capable of excluding and of a dark green hue—serves admirably to enhance the frost from structures containing bedding plants, this being the beauty of the flowers. Turned out of a pot in spring into a couple of bushels of soil the plant grows with much rapidity the long rampant shoots quickly covering a large area of roof space, so that it becomes a prominent feature in a single season. Once established it only requires an occasional pruning to thin and remove old growth, as well as to keep it within bounds.—E. L. O.

HIGHLANDS, TICEHURST, THE RESIDENCE OF DR. NEWINGTON.

WHEN one goes from place to place where horticulture is supposed to flourish, whether it be Lord A, Sir John B, or simply Squire C, we are too apt to find ourselves falling into the same groove. There are grand parterres with flaming colours of bedding-out plants, rows of graperies and vineries, pits of Melons and Cucumbers—all, it may be, arranged on the most orthodox system, but with the orthodoxy very evident; no striking out into pastures fresh and fair, and all under the care of an experienced gardener, the master knowing nothing or next to nothing of his garden; like one with whom I went round his elaborate range of houses, the gardener wanting my opinion on an Orchid as to whether it was correctly named tigrinum or not, struck in with, "Is it any relation of the Tiger Lily?" But there are, on the other hand, places where Genius has made her mark, and of these Highlands is one. I spent a few pleasant hours there with its accomplished owner a little while ago, and wish I could convey to the readers of the Journal any correct idea of it; but I rather felt like the young American lady immortalised by Mr. Punch, who, declining one of the last dishes at an elaborate table d'hôte, said she feit "very considerably crowded." My mental digestion was as much suffering from repletion as that of a City alderman's bodily one would be after a Lord Mayor's feast, but, withal, I shall try to give some idea of some of the things I saw

Highlands is situated about four miles from the Ticehurst Road and Wadhurst station of the South-Eastern line from Tunbridge Wells to Hastings, in the midst of that beautifully wooded part of Sussex stretching down towards Hailsham and Eastbourne. It is, as its name implies, on high ground in the midst of a property of some three hundred acres, and giving facilities by the character of the ground for all sorts of effects in landscape gardening. Here, for instance, we come upon a valley which reminds one of a French plaisance, with its sheet of water, rustic bridges, islands, rockery, and fountains, while all around Conifers and shrubs flourish in the rich strong loam which abounds here. I saw Conifers, such as Abies Douglasii, only eleven years planted, whose growth was something astonishing; and while mentioning these let me say that Dr. Newington's method of moving trees, even large ones, is a most ingenious and successful one. Three large and very strong three-pronged forks are driven into the ground round the tree that has to be moved, a strong leverage is then applied, and the trees are lifted bodily out of the ground with their roots and root fibres unburt, are placed in a trolly or cart and taken to their destination, and are then placed in the hole which has been prepared for them. They feel the removal so little that a death rarely takes place, and I saw some Conifers which had been removed last year which had made longer shoots than those which had remained in the nursery.

The method of growing Grapes adopted by Dr. Newington has also in it much that would interest and perhaps surprise many Grape-growers. He adopts the rod system, but instead of cutting the shoot close back to the rod, and so leaving the one eye to break on which young shoot the bunch is to be produced, he leaves the shoots of the present year about 4 feet long and then fruits these. They will be cut away next year, and others will take their place. Thus he is enabled to choose the plumpest and best bud and the heaviest bunch, whereas on the ordinary system one must be content with the bud pro-duced. Then I saw the Vine on which he had conducted those curious experiments of altering the character of the berries. He had inarched a Madresfield Court with a Black Hamburgh, and had changed the berries to round instead of oblong; and by again inarching it with another variety, I believe Glendinning's Seedling, had brought it back to the oblong shape. Then there was the air-tight vinery, of which something has already been said in the Journal, and on which I can testify the canes were both large, ripe, and promising with their fruit buds. The Peaches here are grown in houses with a very high angle, which retains all the heat, and in which they ripen admirably. I had not time to see one at a little distance 130 feet long, which, however, I hope at some future time to do.

Has anyone ever seen a terrace greenhouse? I never had before, and was agreeably surprised to see one which the ingenuity of Dr. Newington has contrived. It is placed on the top of a ridge and running down each side. There are three or four terraces planted out with greenhouse plants of various kinds; creepers run up over the roof, even Vines are trained on it. It has a very singular appearance from the outside to see a greenhouse running up and down a hill, but the effect from the inside is very original and pleasing. There are few places where it could be attempted, and it would have entered into few minds.

Dr. Newington has been recently building a villa on a part of the estate, and has obtained the stone of which it is built close to the house. The quarry he is about to convert into a rock garden, and, knowing his ingenuity and taste, I have no doubt it will some of these days be a sight worth seeing. There is a large bold mass of rock in the centre, which would be admirably adapted for making an alpine height such as all visitors to York will remember in Mr. Backhouse's nursery. A stream of water will be brought down from the upper part of the ground to form a rivulet through it, along which aquatic plants would flourish. The entrances to it will be carefully concealed by Firs suitable to the locality, reminding the visitor of alpine scenes; while receptacles will be made all around of various sizes and forms, in which alpine plants will be placed, to form, I have no doubt, by-and-by a very attractive feature. In another part of the ground there was a sunken fernery where a large number both of species and varieties were evidently in a flourishing condition.

I should like to have been able to say more of this very remarkable place, but the time of year was unfavourable; and as on the morning I was there there were 18° of frost it was not a very propitious time for making observations. It has, however, whetted my appetite, and through the courteous kindness of its accomplished owner I hope at a more favourable season to spend a longer time there, and to give the readers of our Journal a fuller account of its contents.—D., Deal.

THE EFFECT OF FROST ON HARDY FRUIT TREES.

FROST having come in with such a lion-like grip, we are next season promised the opportunity of judging of its effects on fruit buds when in their dormant state. It is never a desirable occupation advancing any unfashionable theory, and the conclusion of gardeners generally as to the cause of the partial loss of last year's fruit crop proves that my arguments early last season were not fashionable, at any rate not convincing.

My prediction was that we should have no Pears north of York. Perhaps I ought to have stipulated that I meant from trees in the open: and, further, it would have been advisable to have given the names of the varieties judged by. The result quite convinced me that, with this omitted proviso stipulated, my judgment was nearly correct, as out of about forty varieties, nearly all of which bloomed, I only had one variety that carried a crop and two or three others with straggling fruits. In planting I had made the far too common mistake of omitting welltried local varieties, such as the Hessel and others, and had substituted those of higher standing. Of the old varieties grown in the locality the crops have been enormous, but of course the Pears failed to swell to their natural size in such a sunless season; and whether they would have swollen satisfactorily had the season been a dry hot one is a matter of opinion.

For the loss of the crop of, perhaps, eight-tenths of the varieties grown we are told to blame the wet during the blooming period. The wet I concede may have had a detrimental effect, but if to the wet solely we are to attribute failure, then I contend the wet would have affected the bloom of all varieties much alike. This it certainly did not do. Now, habitually, I make it a duty to prove to my own satisfaction if possible anything with which I am connected wherein I have doubts. In my vinery, and after I had discovered that the pith of all the wood of the fruit spurs was blackened, I bloomed over 170 trees; and of the Pears, excepting one or two very small trees of Beurré de l'Assomption that were entirely covered with snow, only Marie Louise d'Uccle bore a satisfactory crop. With one of the former miniature trees that, to begin with, possessed only two fruit buds, I afterwards took first prize at Newcastle, the tree—only 21 inches high—having two very fine fruit. Of the latter, possessing a large quantity of two and three-year-old trees, and having great faith in their superior hardiness, after the frost was gone I carefully lifted

and potted a great many, all of which carried a crop; and with one at Ryhope, carrying nine fruits, I took first prize, there being seven competitors, including two pot Vines in the competition. This to my satisfaction further proved the superior hardiness of the Marie Louise d'Uccle Pear; and my other little pet Pear being protected by the snow, proved that but for the frost all my other very fine collection would also have set their fruit. To further confirm my opinion, and also strengthen my position at the exhibition table, I ordered six Souvenir du Congrès Pears and six Pine-apple Nectarine trees from Mr. Rivers, and, except one Pear which died, the rest set almost every fruit. I thinned the Pears to two and three, and the Nectarines to six and eight on each tree, and the Pears were so very fine that one of the Judges at the Durham Show on being questioned as to why Witherspoon had not taken a prize in the collection of fruit, remarked, "You see he had got those Pears from some nursery!" Such are of the difficulties of us amateurs when exhibiting in our own district; yet in my case, when the Pears were growing they were admired by hundreds of visitors.

When by frost a shrub or tree is killed right out it is at once removed and the cause admitted; but if not quite dead, but still so injured that during summer or autumn the sap is prevented flowing, then the cause of injury is perhaps attributed to various circumstances. My opinion is, had we had a hot May and June then many trees that survived would have died, and I was strengthened in this opinion by both Pears and Apples dying during some hot days in August; and I am also of opinion that the wet more aided than retarded the sap flowing through the injured wood, and also that it prevented many fruits falling in their half-grown state that otherwise would have done so. One certainty, the season has proved which varieties of Apples and Pears suit best our northern locality, and this is valuable information. I am quite prepared to return to the subject if necessary.—JOSEPH WITHERSPOON.

DISEASED TOMATOES.

I HAVE been troubled with a kind of disease on my Tomatoes the same as "D., Deal," mentions in the Journal of October 30th. I have been much annoyed by seeing splendid fruits of Hathaway's Excelsior (a very fine smooth variety) so much diseased as to be entirely unfit for the table or preserving purposes. I find that the disease affects this variety in particular, Orangefield Dwarf being nearly free from its attacks. These two varieties, the latter predominating, were planted in well-manured trenches and trained to a south wall, and I consider that it was owing to the warm aspect that I had so many handsome fruits free from disease. Most of the plants of the Excelsior variety were trained to a wire trellis which divided a long flower border from another portion of the kitchen garden, and here the disease was most destructive to the fruit, although the plants appeared comparatively healthy. They grew strongly till the fruit commenced colouring, when the disease appeared, and the greater part of the crop was totally useless. I had not been troubled with such a failure by disease till the year 1877, and then only in this variety. In looking over my garden memoranda I find off the same number of plants of each variety I only sent into the house 388 fruits of Hathaway's Excelsior against 1287 of Orangefield Dwarf.-F. H. FROUD.

THE FROST.

ACCOUNTS of the frost received by us from various districts shew how general it has been; and in some instances its severity is remarkable. It is to be remembered, however, that thermometers vary exceedingly, and probably in several instances the records are not strictly accurate; still, as they are as likely to be a few degrees too high as too low the returns may be taken as approximately correct, and making due allowances for the variations referred to the frost has been unquestionably severe.

As very few correspondents have given the readings of the thermometer (the correct mode), the majority having quoted the "degrees of frost" in the manner popular amongst gardeners, it will be convenient therefore and intelligible to all if we give the number of degrees below the freezing point to which the mercury or spirit in the thermometers has fallen in various districts.

In the metropolitan district but little snow has fallen, yet the intensity of the frost is apparent by the strength of the ice en the lakes in the various parks, on which thousands of

persons have disported during the past week; the Thames, too, has occasionally been covered with thick floating ice brought from the upper part of the river. In Messrs. Veitch's nursery at Chelsea we are informed that the mercury on the morning of the 7th inst. was at 20° below the freezing point, the lowest during the frost. At Chiswick the weather has been severe. On November 15th the mercury fell to 15° below freezing point. Several Vines in the large conservatory were strangely affected; in some instances every leaf on a single rod being crumpled, while those on other rods proceeding from the same stem were uninjured. On December 2nd the mercury fell 16° below freezing point. On the 5th a similar temperature was registered. This also singularly affected some Vines in the conservatory, although the temperature in the house ranged between 40° and 45°. On the 6th inst. 19° were registered, but on the following day the lowest reading was observed—viz., 22° below freezing point. The barometrical readings have been high—viz., from 30.5 inches to 30.6 inches. Euonymuses appear to be much injured, and much further change is expected.

SURREY.—The temperature has been very low in the vicinity of Kingston-on-Thames during the last ten days, there having been frost and slight falls of snow on almost every day in December, the temperature reaching the lowest on Sunday morning last—viz., 22° below the freezing point. Vegetation has suffered severely.

KENT.—At Barham Court near Maidstone the night temperatures during the frost were as follows—December 1st, 25°; 2nd, 20°; 3rd, 12°; 4th, 14°; 5th, 10°; 6th, 30°; and on the 7th 12° below the freezing point. Much snow has fallen during the week.

ESEEX.—Snow fell at Orsett on November 21st, and much of it lay to Dec. 5th, when it was joined by more, in all amounting to about 3 inches in depth. On the night of December 1st the mercury of the thermometer 3 feet from the ground fell to 23° below the freezing point, on the 2nd to 15°, and on the 7th to 22°. We hear that it has been more severe at other places in the country, but have no reliable data. It is too early to speak of the effects of the frost, but Veitch's Autumn and Snow's Broccoli are much damaged both in private and market gardens; and Celery in the fields, being almost leafless in consequence of the attacks of the larvæ of the Celery fly, must be severely injured.

BEDFORDSHIRE.—The frost during the past week has been very severe in the neighbourhood of Biggleswade, the mercury falling on Saturday night the 6th inst. to 28° below the freezing point. But for the 3 inches of snow which fell on the previous night vegetation must have suffered very much. Ice on the lakes is 5 inches thick. Nearly all outdoor work is stopped. The frost is the most severe that has been experienced for many years.

SUSSEX.—In mid-Sussex the winter has set in with unusual earliness and severity. November 14th brought the first sharp frost; snow fell on the 20th and subsequently. Slight snow showers have been frequent, but it has not been deeper than 3 to 4 inches. The frost continues unbroken. On the 2nd inst. the mercury reached 19° below the freezing point. It was equally cold on the 6th. In a garden on the lower slope of a valley by a tributary of the Ouse the temperature registered is on an average 10° lower, and affords a striking illustration of the importance of selecting high yet sheltered positions for gardens. Curious variations of temperature occurred in the neighbourhood of Uckfield when the cold weather first set in. On November 16th at 7 A.M. the mercury stood at 21° Fahr., on the 17th 42°, and on the 18th 52°, frost and snow following on the 20th. Similar instances of unusual warmth in November occurring in this locality in 1846, 1847, 1852, and 1857 are recorded in Prince's "Climate of Uckfield."

HEREFORDSHIRE.—The weather is very severe, and as yet no snow has fallen to protect vegetation. On the 2nd, 3nd, and 5th inst. the mercury fell to 17°, on the 4th to 13°, and on the 7th to 19° below the freezing point with no signs of a thaw. Much outdoor work stopped.

WARWICKSHIRE.—On Saturday night in a garden at Warwick the thermometer stood at 4°, and in another garden just below it was at zero. Our correspondent says, "No plants hurt indoors, but plenty of coals burnt. Fires made up three times last night. I cannot make my man understand the art of stoking, and it is an art."

NOTTINGHAMSHIRE.—Mr. E. J. Lowe writes to the *Times*, from Highfield House Observatory, near Nottingham, December 7th:—The temperature fell this morning to 2·3 below zero

4 feet above ground, to 3.1 below zero at 2 feet above ground, to 4.4 below zero on the grass, and to 5.3 below zero on the mow. Since 1840 we have only twice had a lower temperature—viz., 1854, on January 2nd, and in 1860 on 24th-25th.

NORTHAMPTONSHIRE.—Mr. Charles M. Caldecott writes

from Holbrook Grange, near Rugby-" December 8th, Saturday night. December 6th-7th was the coldest in my memory. registered 3° below zero, and at 10 A.M. on the 7th the thermometer stood at 4°. Last Christmas my thermometer registered 4°. This house is about 330 feet above the sea.'

LINCOLNSHIRE.—The mercury near Lincoln fell on the 2nd inst. to 27°, on the 3rd to 23°, on the 4th and 5th to 25°, on the 6th to 23° below the freezing point; on the 7th it fell to zero,

and the frost continues, but not so intensely.

DERBYSHIRE.—The following is the record of the minimum night temperature near Burton-on-Trent on the following dates:—December 1st, 11°; 2nd, 24°; 3rd, 14°; 4th, 8°; 5th, 16; 6th, 8°; 7th, 30°; and 8th, 10° below the freezing point. Snow fell on the 1st, 5th, and 6th, but the ground is not thickly covered.

CHESHIRE.—The weather here is very severe. Near Congleton much damage is anticipated amongst shrubs, &c., injury being perceptible already. "We have had," writes a correspon-dent, "an aggregate of 26° of frost more this season up to the present date (December 8th), then we had up to the corresponding date last year. On Friday the 5th we had a heavy snowstorm. Saturday the 6th was the most severe, the mercury falling to 28° below the freezing point."

LANCASHIRE.—At Norris Green Gardens, near Liverpool, the mercury fell on the lat to 11°, the 2nd to 7°; 3rd, 12°; 4th, 17°; 5th, 14°; 6th, 11°; and the 7th to 14° below the freezing point. About 6 inches of snow fell on the 4th, and the ground is still covered with Nature's protector. The lowest register at Worsley Hall, Manchester, was 8° Fahr., or 24° below

freezing point. Six inches of snow.

YORKSHIRE.—In the East Riding, near Sheffield, we learn that the frost has been very intense during the past week, more so than during the whole of last winter. In the low-lying valleys near the river Porter the mercury has fallen to 27 below freezing point. The river Don is frozen over, and on Saturday and Sunday thousands were on it skating. On Monday the barometer was high and the wind north-east. In the North Riding Mr. G. Abbey states that winter set in in earnest on the afternoon of November 29th, snow falling in showers with a keen north wind, but up to December 2nd the readings of the thermometer were not low, varying only a few degrees below freezing point. On December 2nd to the 8th inclusive the mercury fell on the seven consecutive nights to 15°, 20°, 25°, 26°, 24°, 15°, and 7° below the freezing point. The thermometer is 4 feet from the ground, and the situation 841 feet above the seven Special Statement of the seven consecutive nights. 541 feet above the sea. Snow fell at intervals during the week, the total depth being about 10 inches.

CUMBERLAND.-Frost set in near Carlisle ten days ago. On the night of November 29th the mercury fell to 18°, on the 30th to 14°; on December 1st to 12°, 2nd to 25°, 3rd to 15°, 4th to 10°, 5th to 10°, and 6th to 8° below the freezing point. Only about an inch of snow has fallen in this immediate district. A few miles south and east of Brayton, however, Mr. Hammond informs us that snow is lying much deeper, and the ice on the lakes in the county is in grand condition for

DURHAM.-Mr. Witherspoon informs us that at Chester-le-Street at 10 P.M. on the 3rd inst. the thermometer registered zero, and by 4 A.M. 6° below zero; on the following morning it was a degree less. These are correct readings from thermometers belonging to Sir Henry Pottinger and D. H. God-

NORTHUMBERLAND.—At Alnwick Castle the mercury was only 1° above zero on Friday last, at Hexham it fell to 7° below zero, while at Belford we are informed the extremely low reading of 16°(?) below zero was registered, and that at several places the mercury ranged from 5° to 9° below that point.

SCOTLAND.—On the morning of the 3rd inst. frost in the east of Scotland was most intense; in some districts, as at Galashiels, being 3° to 5° below zero. The frost held during the day, and in East Lothian we hear of 3½° to 5° below zero being registered; at Clovenfords 9° below zero; and in the Merse, in Berwickshire, from 8° to 23°(?) below zero. Although a large margin is allowed in the case of most thermometers in common use, yet protected thermometers of the Scottish Meteorological Society have registered below zero.

A correspondent states that at Kelso December 4th will long

be remembered, as 44° and 46° of frost were registered by two gentlemen, and three persons were frozen to death in Berwick. shire. At Tynninghame in Haddingtonshire the mercury fell on the 3rd to within 1° of zero, and on the day following to 3.5° below. Roses, Aucubas, and Laurustinuses are already showing signs of injury.

IRELAND.—Our Clonmel correspondent writes that "it was not until the morning of the 1st inst. that the mercury fell below the freezing point—standing at 28°, while the following morning before sunrise it fell to 22°, and 17° Fahr. at Cottage, Cappoquin, the residence of the Rev. P. Power. Since then, for the last four days the temperature has oscillated between the freezing point and 21° Fahr. I have been taking a look through my flower garden, and find early Anemones that were bursting into bloom will receive a severe check and are much injured, while half-matured growth of Loniceras, Jasminums, Escallonias, &c., are quite blackened. Up to this frost I had blooms of outdoor Roses, Scabious, Helichrysums, Stocks, Pansies, Wallflowers, and Lobelias. All are now gone outdoors.

The lowest temperatures recorded in Dublin this winter were 17° below freezing point on the night of Dec. 1st; on Dec. 7th, 8th, and 9th respectively 12° below that point. This will seem to be but a very slight visitation, but we are within rifle shot of the sea, and the garden is also much sheltered by walls and trees. At other places only a short distance further inland frost has been much more severely felt.

There was no frost in London on Wednesday morning, and

the barometer was falling steadily.

NOTES AND GLEANINGS.

"R. P. B." writes, "If the comparative failure of some of the principal seed crops this year lead to THINNER SOWING it will prove anything but an unmixed evil. It is not so much the waste involved that is to be deprecated, for individually that is not extensive, as it is of injuring the plants in a young state by overcrowding. All our seeds are sown thinner than is generally the case, but even in our case it will be possible to sow thinner still without impairing the value of the crops.

An excellent cultivator observes that "it is wonderful what a quantity of water INSIDE VINE BORDERS require throughout the dull months of winter, when it is necessary to keep the pipes slightly heated. The borders of the late vineries here were watered at the beginning of October, again in the middle of November, and about the beginning of January another application of water will be necessary. At that time the Grapes will be cut and bottled, and the Vines placed in order for another season. We have had an old structure rebuilt this autumn, and prepared for producing Muscat of Alexandria for winter and spring consumption. The border will be entirely inside. By a simple arrangement the vinery will be admissible for growing a large quantity of plants, and by having the Grapes ripe by the beginning of September we expect to have good Muscats till the succeeding April."

- THE members of the WIMBLEDON GARDENERS' 80-CTETY held one of their meetings on Monday night last in the young men's rooms attached to the gardens at Wimbledon House. On this occasion Mr. Moorman, gardener to Miss Christy, Coombe Bank, Kingston, read a brief but practical and instructive paper on the culture of the Chrysanthemum, in which he detailed the system that he has adopted with success. In the discussion which followed Messrs. Lyne and Jordan took a very prominent part, generally corroborating Mr. Moorman's practice from their own experience as growers of the Chrysanthemum.

WE have received from Messrs. Edward Webb & Sons, Wordsley, Stourbridge, a box of PRIMULA FLOWERS in six varieties-namely, white, large, well-formed, and fine; rosy purple, large, and good in colour; bright salmon pink, of good form; dark salmon pink. broad segments, rich, and semi-double; white and reddish pink, very attractive—all good flowers in clear and well-defined colours.

A FLORAL decorator states that CHINESE PRIMROSES of the various shades of red, crimson, rose, and carmine, rank at this season of the year among our best flowers for dinnertable decoration. The soft yet rich tints are much enhanced in beauty when seen by lamplight, for they possess in a high degree that property of "lighting-up well," of which experienced decorators so well understand the value.

- "THE unrivalled Mrs. BOSANQUET," as it was termed

by the late Mr. Rivers, is one of the best continuous-blooming Roses we have. From early summer till late in autumn it keeps up a regular succession of buds and flowers. We cut our last bouquet of it on November 13th from a plant that has climbed some 15 feet high on the side of a building, and it then had a quantity of unopened buds, which in a mild winter would have continued affording an occasional flower till Christmas. It is not an exhibition Rose, but its halfopened buds are so lovely, that whenever space can be had there should be a plant or two under glass as well as on open walls, so as to prolong the season of so useful a variety.

THE value of WALLS FOR DELICATE PEARS has, writes Mr. Luckhurst, been well shown this year. Excellent fruit of Doyenné du Comice are just now ripe from a tree on a west wall—a month later than usual; but the fruit on a couple of fine pyramids was not half grown and quite worthless. It was the same with certain other varieties, and it is also noteworthy that wall trees both on east and west aspects had full crops of useful fruit, in pleasant contrast to the barren condition of most of the pyramids.

- AT the ordinary meeting of the METEOROLOGICAL SOCIETY, to be held by permission of the Council of the Institution of Civil Engineers at 25, Great George Street, Weststitution of Civil Engineers at 25, Great George Street, Westminster, on Wednesday, the 17th inst., at 7 P.M., the following papers will be read:—"On a Sand Storm at Aden, July 16th, 1878," by Lieut. Herbert H. Russell, 8th Regt.; "On a New Form of Hygrometer," by George Dines, F.M.S.; "On Diurnal Range of Atmospheric Pressure," by Richard Strachan, F.M.S.; "Note on a Curious Fracture of a Solar Radiation Thermometer," by G. M. Whipple, B.Sc., F.M.S., F.R.A.S.; "New Sunshine Recorder," by Robert H. Scott, M.A., F.R.S., F.M.S.

— DRACENA ELIZABETHE, one of Mr. Bause's bybrids not long since sent out by Mr. Wills, is valuable for decorative purposes, forming in 48-pots very handsome plants. It is compact in habit, with rather broad and short leaves, beautifully arched, and of a deep green colour, with marginal bands of rosy-red and creamy white, which, in contrast to the deep green, render it very striking and worthy of extensive cultivation.

— AMONG the numerous plants popularly denominated stove climbers, there are few that flower at this dull season which surpass in elegance MANETTIA CORDIFOLIA. This plant when trained up a pillar or rafter and bearing its pendulous orange-scarlet tubular flowers in profusion, is very attractive, and affords a most agreeable relief to the somewhat dull appearance of a stove in December. It is a native of Buenos Ayres, whence it was introduced in 1831, and is occasionally seen under the name of M. glabra.

· In the Orchid house at Kew there is now an excellent display of that useful Orchid CYPRIPEDIUM INSIGNE. The plants are arranged across the stage at one end of the house, and are flowering very freely, the plants being vigorous and This fine old species is of great value as a winterflowering plant, and being of easy culture it should be largely grown in all gardens where choice cut flowers are cherished. and where means are provided for producing them. The flowers remain fresh for six weeks when cut and placed in water.

- In the aquatic house at the Royal Botanic Society's garden, Regent's Park, that queen of tropical aquatics the VICTORIA REGIA still continues to expand its large and beautiful flowers under the careful treatment it receives at the hands of Mr. Coomber. On a recent visit we were informed that the flower then expanding was the twenty-ninth that the plant has borne this season. Probably the flowers will continue opening for several weeks yet.

ANOTHER very beautiful aquatic-viz., PONTEDERIA AZUREA, is also flowering in the same tank as the Victoria. Specimens of the plant received several months ago were placed in the tank and very rapidly spread, closely contesting with the Victoria for space. The plants now occupy a large portion of the tank, and are bearing numerous spikes of bright purplish blue flowers. Specimens were taken to Kew by Mr. Coomber, and these have flowered also. The plant is a native of Jamaica.

AT Mount Edgcumbe we learn there are fine seedling plants, now in pots, of THAMNOCALAMUS FALCONERI, the Bamboo that flowered everywhere a few years ago and afterwards died. Nowhere does the Belladonna Lily make a finer show than there. It is a favoured spot. Desfontainea spinosa makes a fine shrub nearly 6 feet high, and the Camphor Tree the managers of all shows who have not yet adopted the mode grows cut of doors.

THE Committee of the KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY, recognising probably the faded condition of several of the plants and blooms at their late yet excellent Show held on the 27th and 28th ult., have already determined that their next exhibition will be held on November 18th and 19th, 1880. It is to be hoped that nothing will occur to cause a postponement of the fixture, as was the case this year, and which did not prove an advantage to the majority of exhibitors.

- A RECENT telegram relative to the PHYLLOXERA IN SPAIN narrates that vineyards in Malaga, covering ar area of 29,660 hectares, have been attacked by the Phylloxera vastatrix. The pest is increasing in the provinces of Gerona and Catalonia.

- PLUMBAGO ROSEA in the stove and other houses at Norris Green is now producing a fine effect, their light sprays of flower appearing above other plants of a more formal nature add a charm and gay appearance to the whole. Some of the plants in 5 and 6-inch pots from cuttings propagated in the spring have as many as nine or ten shoots. The more heat that can be given them when unfolding their blooms the better they develope.

PROFESSOR MORREN of Liege has issued his annual extremely elaborate LIST OF BOTANISTS in all parts of the civilised world. It also includes the chief scientific horticulturists and the Editors of botanical and horticultural periodicals, the Directors and Curators of the most important Botanic Gardens, the full addresses being given in every case. This work will prove of great value to many whose correspondence is extensive in connection both with botany and horticulture.

It is with regret that we record in our columns the death of MR. W. FARNELL WATSON of Redlees, Isleworth, which occurred on the 30th ult. at the age of 52. Mr. Watson was a patron of horticulture and an important contributor to the London shows, inasmuch as he afforded the means for the cultivation of such plants as Pelargoniums, Calceolarias, Cinerarias, Cyclamens, &c.. which Mr. James has grown so well and exhibited so successfully for a number of years.

- WE regret to announce the death of MR. THOMAS KETTLES on the 2nd inst., at Archerfield Gardens, which he has managed since 1868, when Mr. David Thomson left there for Drumlanrig. Mr. Kettles had been ailing for many months, as we understand from a disease of the heart. Archerfield and Dirleton Gardens were kept by Mr. Kettles in high order, and although of a very quiet and retiring disposition, specimens of Archerfield culture occasionally were to be seen honoured at exhibitions. As a neighbour Mr. Kettles was most obliging, and he will be greatly missed by the gardeners in the county of East Lothian.

THE death also is announced of the DUKE OF PORT-LAND, who devoted so much of his wealth to the improvement of his estate at Welbeck, where gardening has long been conducted on an extensive scale under the late Mr. Tillery, and subsequently by the present competent gardener, Mr. Carr. Welbeck has become famous far beyond its own district and county by the magnitude and original character of the works instituted by its late owner, who expired on the 6th inst., in the eighty-first year of his age.

- WE learn that MR. MCKENZIE, landscape gardener, 1 and 2, Great Winchester Street Buildings, London, and late of the Alexandra Palace, has been appointed by the Corporation of London to be the Superintendent of Epping Forest. There were two hundred candidates for the appointment.

THE demands on some gardens are at all times heavy, nes exceptionally so. This was the case at Melton sometimes exceptionally so. This was the case at Melton Constable, the seat of Lord Hastings, on the occasion of the LATE VISIT OF H.R.H. THE PRINCE OF WALES. During the course of the festivities, including a county ball, Mr. Clarke, his lordship's able gardener, used about four hundred plants for decorative purposes, large quantities of cut flowers, and made 121 bouquets. From thirty to forty bunches of Grapes were dished up daily, and other fruits in proportion. was also a great demand for the choicer kinds of vegetables.

PRIZE CARDS AT EXHIBITIONS.

Mr. BARDNEY has, on page 423, directed attention to an important subject, and one which is worthy of the attention of of affixing the prize cards which he there describes.

is commonly termed the blind system, or judging under numbers, is fast becoming obsolete; still the plan is adhered to by the managers of one or two important provincial exhibitions, and is continued at several smaller shows in various At a recent large show that I visited it was almost painful to witness the rushing of officials backwards and forwards to and from the classes to the secretary's department to obtain the names corresponding to the numbers to which prizes were awarded, and placing the prize cards on the right collections. The work was evidently ardnous, and caused great anxiety lest mistakes should be made; indeed, notwithstanding the care exercised some were made, and were with more or less difficulty rectified. the advantages of the system described by Mr. Bardney being mentioned to the secretary he replied with a shake of the head, "Ah! the plan is no doubt good, but then we do not want the judges to know whose collections they are judging." My reply was, "Of course you do not, neither do the judges want my reply was, "Or course you to not, neither do the judges want to know, nor indeed are they more likely to know under what may be termed the South Kensington plan than under the intricate and labour-entailing mode of exhibiting under number and filling in the names of exhibitors afterwards, when such work is seldom properly done or completed before the inruth of spectators."

The plan described by Mr. Bardney is not a tentative one, but its practical worth is thoroughly established. It is safer, simpler, and more generally efficient than any other mode that I have seen, and I have had the opportunity either as judge or journalist of attending as many shows during the past few years as probably anyone in the kingdom. I can only remember one or two shows where the blind or numbering system has been adopted that mistakes have not been made, and in none where delay has not occurred in affixing the prize cards; but in the majority of cases errors have been common, and in some instances very annoying to exhibitors. At the Royal Horticultural Society's Provincial Exhibition at Preston, where Mr. Barron had no share in the department in question, there was nothing but confusion in affixing the prize cards, and mistakes were deplorably frequent; indeed had not many of them been promptly pointed out by the representatives of the Press, or had the reporters merely copied the awards in a perfunctory manner, the accounts of the show published in the horticultural papers would have been startlingly inaccurate.

And now comes the question, How did the reporters recognise the errors? The answer to that very natural question proves the uselessness of numbers for the purpose for which they are employed. It is the fact that the representatives of the horticultural press and all the best and most experienced judges know the plants and collections (if they take the trouble to examine the exhibits for that purpose) of all the chief and most frequent exhibitors as well as they know the exhibitors themselves. Exhibitors as well as they know the exhibitors themselves. But, as I have previously observed, the judges do not wish to know whose collections they are judging; and, further, I do not hesitate saying that if they did know their verdict would not be influenced in the alightest degree. The judges who usually officiate at the principal horticultural shows are men of honour, and would no more think of not doing what they conceive to be strict justice than would Her Majesty's Judges learned in the law in the cases brought before them. learned in the law in the cases brought before them.

The idea which appears to yet linger in the minds of some show managers, that judges of reputation would turn up a card to see an exhibitor's name when discharging their duties and so be influenced, is utterly and unquestionably fallacious. I can truthfully say that I have seen thousands of collections judged, and not in one instance have I seen a judge turn up a prize card, indeed that is the very last thing he would think of doing; and, further, I have neither seen nor heard of a single case of dissatisfaction in reference to the mode of judging referred to by Mr. Bardney, while mistakes are extremely rare, and the prizes are affixed as the judging is done with the greatest cale-rity, and the entire system works smoothly and satisfactorily.

Besides, when a card containing the name and address of the exhibitors, with the class, description, and number is placed before every collection, the exhibitor has the recognition to which he is justly entitled. Many collections only fail by a point or two to obtain prizes and yet are highly meritorious, and why should a competitor who really stages in a commendable and praiseworthy manner not be credited with his work if he chooses? An exhibition, too, is far more interesting to spectators when they can see the names of the competitors in e various classes, whether they have received prizes or not. When numbers only are placed on the exhibits, the names

of the competitors being thus pointedly hidden from those who adjudicate, it is a silent but none the less emphatic mode of informing men who are as honourable as the officials themselves that they cannot be trusted. On all grounds, therefore, it is to be hoped that the blind system founded on mistrust will soon be abolished. In some small local shows, judged by local men, some masking of the exhibits and competitors may be desirable, but as a rule the employment of local judges is a mistake, It is invariably better to secure judges of public reputs, and to trust them, and they are sure to discharge their duties with strict justice and impartiality.-J. WRIGHT.

GELASINE AZUREA.

In reply to a correspondent, "J. B.," who desires a description of the above plant, bulbs of which he has received from Belgium, we cite the following from a previous issue of the Journal:—The Gelasine azures was first introduced into this country in the living state in 1887, having been sent from Boston, U.S., to the collection of the Dean of Manchester at

Pig. 45. — Gelegipa

Spofforth, where it flowered and ripened its seed. It is a mative of the Banda Oriental, and the province of Rio Grands, where it occurs in stony places. It is sufficiently hardy to bear exposure in this climate, especially if covered with a few pear exposure in this climate, especially if covered with a few dry fern leaves, and, like some of the Irises, retains a part of its foliage through the winter. It is readily raised from seet, and young plants will produce flowers the second season; so that it will, we hope, soon be classed amongst the commonst of our hardy bulbs. The seeds germinate most freely when sown as soon as ripe, on a gentle heat, and the seedlings should be kept growing through the winter. The plant also produces offsets, by which it may be increased.

It grows from 18 inches to 2 feet high, the flower stalk being

It grows from 18 inches to 2 feet high, the flower stalk being furnished with four bracts placed at regular distances, the upper one being leaf-like. The leaves are from 1 to 2 feet in leng and about 1 inch in breadth, pointed at their extremities, and plaited, as in the case of the Tiger-flower (Tigridia Pavonia). The flowers are produced from a spathe, which is aborter than their footstalks. The funnel-shaped limb of the blossom is divided into six regular segments, alternately smaller, which are united at the base into a tube; each segment is marked

with white at its base, on which are several black spots, the segments themselves being of a deep blue tint. The three filaments are united into a short tube, in other words monadelphous, the authors tapering upwards, and opening by their sides. Style simple, divided into a three-lobed stigms. Capsule egg-shaped, opening when ripe at the top by three valves. Seeds angular, flat at top, tapering downwards. One of the divisions of the flower, and also the monadelphous filaments, are shown separately in the engraving.

BEDFORDSHIRE TWIN APPLE.

HITHERTO the only variety of Apple that has produced fruit of a twin character has been the Cluster Golden Pippin, but that which we now introduce for the first time to public notice is another, and of a very different kind. The Bedfordshire

Twin Apple was brought to our notice in 1877 by Mr. George B. Clarke, chemist, of Woburn, Bedfordshire, who sent some specimens which did not convey the whole of the characteristics of this variety. This year Mr. Clarke has again sent us some better examples, showing the fruit in its two characters of single and double. The history of the tree is thus supplied

by Mr. Clarke:—
"I have been over to Mr. F. Bowler, butcher, of Husborne Crawley, about a mile or so from here, where the said twin-Apple tree is growing, and have selected a few fresh specimens of the fruit and have sent the same off by fast train this evening. The fruit is smaller this year than it generally is, and has been gathered now about a fortnight. Mr. Bowler informs me that it will keep sound in ordinary seasons until the following July.
"With regard to the history of it, he informs me that he had

Pig. 46.-BEDFORDSHIRE TWIN APPLE.

the grafts about twenty years ago from an uncle of his (who was a gardener), from the garden or orchard of a Mr. George, who lived at a place called Bythorne, near Huntingdon. It is very late in coming into bloom, and generally has a crop of Apples on one side or the other every year. This year it fruited on the side of the tree facing the north-east; last year the southwest side. I believe a nurseryman of the name of Mr. G. Handscomb, at Woburn Sands, near the railway station, had some grafts last season, and has about thirty or so of them taken, so that anyone desirous of having the Apple will be able to get one, unless the demand exceeds that quantity. The tree of Mr. Bowler's was grafted near the root, and has an upright stem or trunk for about 6 or 7 feet and then branches out on all sides. I may may it blooms in very close clusters and a very white bloom, which makes it look very conspicuous at

The fruit is generally about one-third larger than is repre sented in the figure. The single specimens are roundish-oblate, obtasely ribbed, especially round the crown. The skin is bright red, mottled with a darker shade of the same colour, and this extends almost over the whole surface, except in such places as are shaded, and there it is greensh yellow with faint broken-streaks of red. The eye is closed, with convergent segments, and set in a shallow plaited depression; sometimes it is nearly level with the surface. The tube is short, funnel-shaped, and

the stamens median. Stalk very short and deeply set in a wide, shallow, saucer-like hollow. Flesh very firm and solid, not very juicy, briskly flavoured; cells closed. The twin fruits vary considerably in the degree of the twin development. In some Apples there is the mere suspicion of a swelling sur-mounted with a small "eye;" others have a small twin the size of a hazel nut attached to one four times its size, and so on in progressive development tall the pair are uniform in size, as they are represented in our engraving. It is an excellent cooking Apple.

PROTECTING PLANTS IN COLD FRAMES AND

Snow being a good protection for plants against frost, we are surprised that some gardeners are so studious about its removal from the lights of cold frames and pits wherein are wintered half-hardy plants. Placing protecting material on frames at night and taking it off by day is an altogether needless proceeding, and with a good thickness of snow over the lights we have a protective substance equal to any other of the same thickness, by banking up snow against the sides and the same thickness; by hanking-up snow against the sides and ends of the frames or pits the plants will be safer than under the process of alternately protecting and uncovering. Provided no artificial heat is employed all plants, no matter whether

they be Calceolarias, Pansies, Carnations, &c., Cauliflowers, Lettuces, &c., are just as well in darkness from the time of frost and snow setting in to that of a general thaw, whether the frost's duration be prolonged from days or weeks into months. The only precaution necessary is to keep them from air and light until they are thoroughly thawed. It is a mistake to uncover the frames upon every appearance of a thaw, which only tends to injure the plants.—G. A.

THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 28

In the early articles of this series some account was given of various interesting localities to the north of the metropolis. and we would now add to our previous notes a few gleanings that have been gained subsequently. During the comparatively short period since we commenced to write upon this subject the builders have been actively bringing about changes which may be advantageous to ground landlords, but which, as a correspondent of a popular magazine has regretfully observed, substitute for fields and gardens "a wilderness of bricks and mortar," less pleasing to the æsthetic eye. Clearing the ground, too. is now often root-and-branch work, whereas some fifty or sixty years ago when nurseries or small parks were devoted to building purposes, many of the trees and shrubs were left, so that in squares and gardens formed about that time may be seen exotics of a hardy kind, which are descended from some of the first specimens received by London nurserymen who had land on the northern heights early in the eighteenth century. At present the house speculator is apt to be merciless, and if remonstrated with when preparing to cut down some venerable or handsome tree, is quite likely to reply in the words used by one to whom Tennyson, our Laureate. addressed himself at Hampstead, in a protest against such destruction, "Trees is ornaments, what we wants is utility.'

Hoxton, a district that to us seems almost a part of London proper and not suburban, certainly not rural, is referred to by Gibson in his "Survey of the London Gardens," made during the reign of William III. Long after his time Hogsdon (for such was the original name), was still so much of a village that we find an author wondering whether the City would ever reach it and swallow it. This the City has done without satisfying its appetite. Here once were the grounds of Ricketts, Pearson, and Darby. Of the three men Gibson appears to give precedence to Darby, who was celebrated as a cultivator and importer of evergreens, a demand for which was increasing towards the end of the seventeenth century. He tells us that Darby raised striped Hollies by inoculation, and like a sensible man, he kept a book of dried specimens, or probably several, as a record of plants reared in his establishment. Later in horticultural history we have Thomas Fairchild a resident here, though we cannot say whether he was a successor to one of the three nurserymen mentioned by Gibson. He had not only a nursery but also a vineyard, and is remembered as the author of "The City Gardener." The Royal Society honoured him by hearing a paper of his on the motion of sap in plants. It is noteworthy that he, dying in 1729, bequeathed an annual guinea for a botanical sermon, a sum which was raised to three by subscription as being insufficient. Bassington had a small nursery at Kingsland in Gibson's time, and near the road to that place were the "City Gardens, which have been referred to as being an early instance of allotment gardening, for in the period of the Tudors, or before, the citizens had plots here to cultivate culinary plants and herbs. A map of 1810 exhibits the space occupied by the "City Gardens" still undisturbed, and near them is Hemlock Barn, perhaps significant of the growth of weeds on some of the waste ground there. Eastward, towards Hackney, is shown a wide extent of garden land intersected by a winding lane. But in the peaceful years following Waterloo building and road-making went on rapidly, and the market gardeners moved farther to the north and east. Those who commenced, little dreaming how streets would multiply, in more instances than one named their new rows of houses "Pleasant Place," or "Prospect Terrace," soon ludicrously inappropriate.

Several very old residents in London remember well two

farms that were formerly close to the bustling thoroughfare, Oxford Street, on its north side. Some of the land was used

be included in the Regent's Park. Messrs. Alsop and Whelar held these farms during the latter years of the eighteenth century. In saying, however, that this land is covered by buildings, we, of course, except the space given to those squares, which are a marked feature of north London. In a few instances these have been occupied by nurserymen, as was Euston Square until recently. This had received the name of the "Bedford Nursery." and announced itself as "established in 1801," but a map of Marylebone dated 1778 shows a nursery on the same spot. Ampthill Square, at first "Russell Crescent," was probably formed into a nursery about 1808, not earlier, and this ceased to be a nursery in 1878, when there was a sale of Palms, Yuccas, Dracenas, Araucarias, &c., the last proprietor being Mr. Robert Green.

Concerning Islington and its vicinity we would note further that its nurseries from the local history appear to have been most flourishing about seventy years ago. The name of Bassington is recorded as the holder of some twenty acres of market-garden and nursery ground there, no doubt a descendant of the Bassington whom Gibson visited in the seventeenth century. Mr. Townsend in 1806 took for nursery purposes five acres of land which had been the practice ground of the Islington Volunteers, and he had also land at "Frog Lane." His nursery we presume to be identical with the one now occupied by Mr. Solomon, situate between Upper Street and Park Street. Amongst the nurserymen of that period we find Messrs. Barr, Parker, and Watson, but their names have not connected themselves with any specialities. In one of the curious advertisements in the "Connoisseur" (March 4th, 1756), we read that Mr. William Redmond of Islington, has produced a fine Auricula called the "Triumph," offered plants at half a guinea each, so we may conjecture he had then what our ancestors styled a "sale garden." An old tavern at Canonbury with the sign of the "Rosemary Branch" is, as in several other places near London, a reminiscence of some herbary or physic garden that has long vanished. Loddiges' nursery at Hackney has been already mentioned; a few more particulars may be given concerning a place to which visitors from afar resorted as to one of the principal sights of London. It was so contrived that the buildings enclosed three sides of an open space. Entering a series of hothouses the visitors passed to the grand Palm house, thence to the "dry stoves for bulbs," beyond was the double Camellia house, and greenhouses for various plants. Within the area were arranged frames, numerous American and herbaceous plants not under glass, and collections in pots ready for sale. On the north side were propagating pits and plantations. The arboretum On the north was considered to be very curious; it was composed of a number of winding paths with short connecting paths at intervals and the termination of the walk brought the visitor into another circle laid out with grass paths and flower beds. In this arboretum on one side of the walk were trees and shrubs, on the other Roses and mixed herbaccous plants. The trees were arranged according to genera and species, with varieties also, and behind the named examples were placed stools and stocks, or young specimens for disposal. All the names were painted on bricks half sunk in the earth. Perhaps the mantle of the once famous Messrs. Loddiges in north London may be said to have fallen on Mr. B. S. Williams of Holloway, whose Victoria and Paradise Nurseries, though only about three acres in extent, are nearly all covered with glass, and the specialities are numerous and varied, including Orchids, Ferns, Palms, and many stove or greenhouse plants. These nurseries have been in existence about twenty-four years.

Inspecting the Stepney of the present time, as one obtains a view of it from the railway that passes over it, it is not easy to picture it to oneself as a beautiful bit of woodland belonging to the Bishop, into which the Londoners strolled during the summer to hear the birds sing and to gather wild flowers. When cleared of its trees most of it became pasture land. Lyons notes in 1794, that of its 1500 acres not more than 130 were brought under cultivation, and of this land that had been ploughed up the market gardeners held about 50 acres. Houses and factories, as was to be expected from the growth of London, gradually reduced the garden ground during this century. At Bethnal Green, a hamlet of Stepney, there were also market gardens, and some of these remained until 1847 or 1848, principally in the neighbourhood of Cambridge Road. To horticulturists this locality is memorable as having the for growing vegetables, and part was grass. In 1776 the open ground reached nearly to Tottenham Court Road, now it is all built upon except the portion which appears by the maps to beyond Whitechapel there was formerly a nursery frequently referred to by writers upon exotics during the eighteenth century. It was founded by one Gordon about the middle of that century, who made it over to his sons James and William in 1776. Next it was the property of James Gordon and two others, Denner and Thompson. Subsequently Thompson became the sole owner. When Loudon visited it in 1835 only a small portion of the original ground was left untouched, but he saw what was believed to be the oldest Salisburia in England, also aged Magnolias, an old Ailantus, Cork, and other Oaks, and large Tea plants growing and thriving in the open air. Gibson has an allusion (1691) to a Clements of Mile End, about whom we only know that he had many curious "greens," and made White Muscadine and Frontignan wine from Grapes of his own producing. We have, by the way, even yet a Vine Nursery not far from Mile End, in the Hackney Downs Road, but the atmosphere of the district does not seem promising for Vine culture at present. There are yet various market gardens to the east of London; their date is comparatively modern, and their history not remarkable. We might, however, add here, as an ascertained fact ere we conclude, that down to the year 1850 at least those horrible inventions known as mantraps were occasionally set in London orchards or market gardens. These were of two kinds; the humane (?) trapsimply broke the leg of the person caught, the other sort not only did that but also crushed the bone !—C.

NOTES ON VILLA AND SUBURBAN GARDENING.

VERY little can now be done out of doors; all planting, trenching, and such work have to be suspended for the present. Wheeling manure on the ground between Raspberries and other fruit trees, and on vacant spaces of ground ready for digging-in, is one of the best employments during such severe weather as we are now experiencing. It is warm employment for the men, and the manure is carried so much lighter and cleaner than during wet weather. In gardens where many trees abound leaves may yet have to be collected, for they have clung very pertinaciously to the trees this year. Place the leaves in a heap in a frame yard, and when thoroughly mixed with some long stable manure the mixture will soon form suitable material for making hotbeds for Cucumbers, Potatoes, Radishes, Carrots, and other vegetables that are required to be supplied early in the year. In many gardens complaints, especially in small villa gardens, are sure to be raised this winter over the scarcity of vegetable crops, for in the majority of such places there is rarely sufficient area of kitchen garden to supply the demands of the family during a severe and protracted winter. Crops planted or sown in accordance with the method and directions in ordinary seasons are this year fully a month or six weeks later than usual, so late that in many cases vegetables that would otherwise have proved useful are now completely destroyed. Veitch's Autumn Broccoli are only just commencing to form their heads; Celery is small, and severely infested with the Celery fly; Turnips, unless sown very early, have not reached a size suitable for drawing; Beet is generally small, and Brussels Sprouts very late, so vegetables generally must be scarce; it will therefore become the duty of everyone to make whatever amends to possible by forcing, and much disappointment may be averted by timely consideration and action.

Asparagus, Seakale, and Rhubarb are the easiest of vegetables to procure by artificial means if strong and sound roots be selected. The first of these is possibly the most important vegetable of the three, and does not require a strong heat to cause it to push quickly—in fact, the more gently it is forced the stronger and better flavoured will be the shoots. A good plan is to make up a hotbed principally of leaves, over which an ordinary garden frame is placed, and the roots are planted thickly together, covering them with some light soil. Many cultivators sow Radish seed over the surface, young and sweet roots being thus obtained. Wood's Early Frame Radish is a good variety for this purpose. Seakale is forwarded in several ways. The two simplest are the lifting of some strong roots, placing them in boxes under the stages of a stove, and covering them over to exclude light; and by placing an inverted pot over the crowns on the ground as they are growing, and covering the pots with a mixture of manure and leaves, the gentle warmth from which will excite growth. The latter plan is to be preferred when large supplies are required. Those who have the advantage of a Mushroom house have only to lift sufficient roots and place them therein to procure fine blanched crowns. Rhubarb is forced in a similar way, and is most appreciated when of a bright pink colour. A temperature of 50° to 60° is sufficient to procure well-flavoured produce, and the temperature should never rise above the last-named degree.

GREENHOUSE AND CONSERVATORY.—Sufficient fire heat must be maintained in these structures to exclude frost, but by no means allow an excessively dry heat, or many plants will become dry. Any water required should be given early in the morning,

so that there is some chance of the soil drying before the evening. Chrysanthemums, which have kept these structures so gay during the past six weeks, are now fading fast, and as they go out of flower should be cut down and removed, reserving the roots for a supply of cuttings for next year, cuttings of which may be inserted in small pots in light soil any time from now till March. Many good growers take the earliest cuttings obtainable. Rhododendrons, Azaleas, Deutzias, and several other easily forced shrubs must be forwarded to take the place of the Chrysanthemums. Bulbs will also be coming into flower, which by the new year will make the conservatory gay.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE ordinary routine of operations in this department being interrupted by snow and frost, it becomes necessary to turn attention to matters which can under such circumstances be executed. Amongst these may be enumerated the preparation of Pea sticks, stakes in suitable sizes for all purposes, pegs for layering, &c., and twigs for laying-in the summer growths of such wall trees as Peaches, Nectarines, and Morello Cherries. The clippings of Privet hedges will be found most suitable when tied in bundles to straighten, and placed in a shed where they will become somewhat hardened. Potatoes intended for planting in the ensuing season should be placed in single layers and kept cool, frost being excluded, so as to prevent early growth. The emptying of plies and the turning and mixing of compost heaps will afford plenty of employment.

HARDY FRUIT GARDEN. In favourable weather push forward the operation of pruning, nailing, or tying-in wall trees. In pruning old trees, especially Apricots, Pears, and Plums, overgrown, old, and barren spurs should be gradually cut back so as to keep the fruitful buds as close to the stem as possible. Some gardeners object to the pruning of Apricots until the buds are beginning to swell in spring, as when pruned in early winter the extremities of the shoots are liable to die should the winter prove severe. Such, however, is not our experience, for beyond the shortening of projecting spurs the removal altogether of worn-out spurs and shoots, and thinning where they are too crowded, there will not be much to do in autumn if summer pruning has had proper attention. If the trees are not unfastened from the wall they must be closely examined for ties or shreds that are too tight. The damage inexamined for ties or shreds that are too tight. flicted by tight ties, a nail injuring the bark, and not over-careful use of the hammer, is often serious, especially to Apricots, Cherries, Plums, and the Peach and Nectarine. Peaches and Nectarines may now have the bearing wood of the past season removed, and may now have the hearing would of the past season removed, and any old branches which can readily be replaced by younger and more fruitful growths. Beyond this and cutting back growths to originate shoots at the required places for regularly filling up the wall space no further pruning is needful; for, as a rule, the more fruit trees are cut in winter the more they will grow the following season and be correspondingly unfruitful. Ap Pears, Plums, and Cherries, whether grown as espaliers, bushe pyramids, may now be pruned with advantage, staking and tying as may be necessary. To make handsome and fruitful trees, pyras may be necessary. as may be necessary. To make nanosome and truttul trees, pyramids and bushes should be moderately well thinned, as where hard stopping is practised during summer they are apt to become crowded, especially in the centre, and for want of air and light not infrequently die or become so weakened as to seriously affect the prospect of a crop of fruit or its maturation. If there be any scale on Pear or Apple trees they may be dressed with paraffin, applying it with a brush, taking care that it does not run down to the roots. There is some danger of applying paraffin down to the roots. There is some danger of applying paraffin where the wood is unripe. A solution of soft soap 1 ib. to a gallon of water, adding a wineglassful each of spirits of turpentine and methylated spirits, applying with a rather stiff brush, will destroy scale. Moss or lichen may be destroyed by sprinkling them with quicklime whilst wet. The Raspberry is one of the most with quicklime whilst wet. The Raspberry is one of the useful of hardy fruits and is variously treated, but all growers agree in its requiring deeply trenched highly manured ground, planting in lines from 4 to 6 feet apart, and 3 to 4 feet from plant in the standard of the same distance in each case being preferable. Some to plant, the larger distance in each case being preferable. secure the canes to stout stakes 44 to 5 feet above ground, and cut the canes back to the height of the stakes, whilst others dispense with the stakes, merely tying the canes together. Others tie the end of one set of canes to the one next to it in the line, so that each two plants form an arch of bearing canes. Others train the canes to light rails or strained wire similar to espailers; and some merely thin-out and shorten the selected canes, employing no support except it be a light rail or strong tarred string to support the outside canes. The various systems each have ad-We have seen good crops produced by all. The canes vantages. We have seen good crops produced by all. The canes should be thinned-out from four to six to each stool, selecting the trongest and best placed. A good dressing of manure should be given and be dug or forked-in, merely pointing it in near the stools, but between the rows and plants it may be placed lower down, but the less the roots are disturbed the better. The pruning of Gooseberry and Currant bushes should also be proceeded

with, though where bullfinches abound many persons have so great a dread of their ravages as to defer the pruning until spring. In pruning, the bushes should be kept open in the centre, and the shoots on the main branches cut back to within an inch or rather less of their base, having the branches from 9 to 12 inches apart, shortening the terminals as may be necessary to form symmetrical bushes, whilst those that are as large as desired may be closely spurred-in. Black Currants should not be spurred, but have the old wood well thinned out and any old elongated growths shortened. After the pruning is completed a good dressing of manure should be applied and be dug or forked-in.

FRUIT HOUSES.

Cucumbers.—In the present severe weather the progress of Cucumbers is very slow. A regular temperature may be set down as of first importance. The night temperature may be 65°, and if Cucumbers is very slow. A regular temperature may be set down as of first importance. The night temperature may be 65°, and if it fall 5° during the night in severe weather it will be better than a higher temperature, 70° to 75° by day will be suitable, the bottom heat being steadily maintained at 80°. The water applied to the roots must be warm. Continue to remove old foliage and exhausted growths from the autumn-fruiting plants, but do not stop the growing points too much for the next two months. Avoid overcrowding and overcropping, giving a liberal encouragement to the roots by applying fresh compost as they protrude through from time to time, and an occasional watering with weak liquid manure. Remove all tendrils and staminate flowers from the winter-fruiting plants. the winter-fruiting plants.

Peaches and Nectarines.—Fire heat may now be applied to the earliest house if it has been duly closed and prepared for forcing; but the night temperature must not exceed 50°, and should be kept at 40° to 45°, 55° not being exceeded by day by artificial means and 65° from sun heat, 50° from fire heat being sufficiently high by day in dull weather, as the best results are obtained by gentle excitement of the trees in the early stages of development. Admit air when the temperature inside is 50°, and increase the Admit air when the temperature inside is 50%, and increase the ventilation with the temperature. Syringe the trees, walls, &c., with water of the same temperature as the house on fine mornings, and again in the early part of the afternoon. Carefully avoid sudden changes of temperature and a stagnant vitiated atmosphere after the buds have started growing. Proceed with pruning, washing, and tying-in the trees in succession and late houses, keeping the houses cool and well ventilated. Some take the very early fruit from trees in pots, and where trees have been potted and grown in heat the previous season so as to acquire an early and grown in heat the previous season so as to acquire an early habit for forcing they answer fairly well. The pots may be plunged in slight bottom heat if there be a pit, or a fermenting bed can be made on the floor of the house, the temperature at the roots not exceeding 65°. Hales' Early is far the best early Peach, but Early Beatrice is several days earlier. Early Alfred and A Bec are good early kinds, and to succeed them Royal George (the best of all for forcing), and Grosse Mignonne, Noblesse being excellent. Lord Napier, Hunt's Tawny, Rivers' Orange, and Rivers' White are suitable Nectarines.

White are suitable Nectarines.

Figs.—There must not be any further delay in starting the trees in pots that are to afford ripe Figs early in May. The culture of trees in pots for early forcing is to be recommended as preferable to starting trees which are permanently planted out at this early season. Moderate heat at the roots is highly beneficial provided it be regular and does not exceed 70° in the early part of the forcing process, as a higher temperature has a tendency to encourage growth too rapidly; therefore avoid bringing up the materials too high if the pots are stood on pillars of brickwork as previously advised, or do not plunge the pots deeply into the bed if the heat exceed 70°. See that the balls are thoroughly moist before the pots are plunged, and if the soil is very dry immerse the pots in water. Let the night temperature be 50°, and 55° by day from fire heat, advancing to 60° or 65° from sun heat. Keep the atmosphere moist by sprinkling the usual surfaces, and syringe the sphere moist by sprinkling the usual surfaces, and syringe the trees twice a day, and above all give the trees, a position where they will have the advantage of every ray of light practicable. Ventilate early Fig houses intended to be started next month, merely excluding frost, proceeding with the cleaning and tying of

trees in later houses.

PLANT HOUSES

Conservatory.—Summer-flowering climbers, such as Passifloras, should be well cut back and have the growth thinned out so as to admit as much light as possible to the plants. Any plants, as Palms, &c., infested with white scale should be cleaned as opportunity Sc., intested with white scale should be cleaned as opportunity offers. The readiest means is to apply methylated spirit with a brush, and it may also be destroyed by nicotine soap 8 ozs. to a gallon of water, applying the solution with a brush, which will destroy and remove the pests, the plants being afterwards syringed or sponged with clear water. To have a good display of flowers in this structure it is necessary to maintain a rather higher temperature than is usually accorded greenhouse plants at this season. this structure it is necessary to maintain a rather higher tempera-ture than is usually accorded greenhouse plants at this season. This is more particularly needful with plants which during their growth require a stove temperature, but which are employed when in bloom for the decoration of this house. A temperature of 50° by day and 45° at night will be suitable by artificial means, and 5° less on cold mornings may be allowed without injury to plants that

are brought from warmer quarters providing they have been grown in plenty of light. Of greenhouse plants now flowering the following are the best:—Acacia platyptera, A. oleifolia elegans and A. Riceana, Abutilon Boule de Neige, A. Darwini, Aponogeton distachyon (aquatie), Coronilla glauca, Cyclamen persicum vars, Cytisus racemosus, Correa Brilliant, C. cardinalis, and C. magnifica; Echeveria retusa, Eupatorium riparium, Erica colorans, E. gracilis autumnalis, E. grandinosa, E. hyemalis, E. Lambertiana, R. melanthera, E. scabriuscula and E. caffra; Epacris ardentissima, E. Devoniana, E. delicata, E. Eclipse, E. hyacinthifiora var, E. Vesuvius, E. Lady Panmure, E. lineata major, E. The Bride, and E. Viscountess Hill; Fuchsia Dominiana, F. Beauty of Trowbridge, F. splendens, F. serratifolia multiflora, Libonia floribunds, are brought from warmer quarters providing they have been grown bridge, F. splendens, F. serratifolia multiflora, Libonia floribunda, Luculia gratissima, Zonal Pelargoniums in variety, Vesuvius being far the best scarlet, and White Clipper the best white; Rogiera gratissima, Monochestum ensiferum, Primula sinensis in variety, Salvia splendens, Statice profusa, Veronica Andersoni variegata, which with Chrysanthemums and early Camellias will afford no which with Chrysanthemums and early Camellias will afford no insignificant display, aided by Lapagerias, Habrothamnuses, Tacsonia Van-Volxemi as climbers, and hardy plants, such as Schizostylis coccinea, Anemone japonica alba, Helleborus niger maximus, H. orientalis, Violet Victoria Regina, V. De Parme, and V. Maris Louise; the Roman Hyacinth, and Paper White Narcissus being also invaluable. At this season Mignonette (Miles' Spiral is far the best) is also indispensable. Then we add to the preceding plants those that require to be advanced in a temperature intermediate between a stove and greenhouse, such as Bouvardias, Carnations, Epiphyllums, Heliotropes, and Richardias, with forced Azalea indica, and plants from the stove, such as Poinsettias, Euphorbia jacquiniæflora, Gesnera zebrina splendens, G. exoniensis, Centropogon Lucyanus, Musseenda frondosa, Dalechampia Roezliana rosea, Scutellaria Mocciniana, Plumbego coccinea, Thyrsacanthus rutilans, Aphelandra aurantiaca Roezlii, Dalechampia Roezliana rosea, Scutellaria Mocciniana, Plumbago coccinea, Thyrsacanthus rutilans, Aphelandra aurantiaca Roezlii, Toxicophicas spectabilis, Burchellia capensis, Eranthemums, Begonia insignis, B. Saundersi, B. parviflora, B. manicata, B. hybrida multiflora, B. nitida odorata, B. fuchsioides, &c., besides plants such as Tydæas, which by not being started until June flower finely at this season; in fact, we kept back some Achimens until August, and they are now very bright, and where plants of Gardenia, Eucharis, Pancratium, Imantophyllum, Francisca calycina major, and Amaryllis have been prepared by an early growth, and given a suitable rest, there is no difficulty in having them in bloom at this season by placing them about six weeks previously in a moist heat of 70° to 75°. Cinerarias are also very bright, and are easily obtained by sowing the seed early, the blue and red varieties being very useful for cutting. Berryproducing plants, such as Solanums, Ardisias, Rivinas, and Capsicums, are also of considerable utility.

Forcing House.—Pot Musk and place the pots in this stru-

Forcing House.—Pot Musk and place the pots in this struc-are. Sweet Briar should also be grown, introducing a few plants ture. Sweet Briar should also be grown, introducing a few plants from time to time so as to keep up a supply of sprays for cutting. Introduce a few Hyacinths, Narcissuses, Tulips, Jonquils, and Scillas to meet the probable demand and maintain the succession, assigning them positions near to the glass. Lily of the Valley, Solomon's Seal, Spirseas, and Dielytras should also be introduced at regular intervals, and the same with Azaleas, Rhododendrons, Lilacs, Deutzias, &c., which should be forwarded gently to allow of the gradual development of the buds.

Orchids.—The most inactive period being reached, be careful not to employ more fire heat than is necessary to keep the temperature of the East India house about 65° by day, and 57° or 58° by night, Mexican house 51° to 60° by day, and 50° by night, the cool house 50° by day, and 45° at night, allowing a few degrees rise from sun heat. Very little air is requisite now, and when given must be by the bottom ventilators, or so as not to subject the

from sun heat. Very little air is requisite now, and when given must be by the bottom ventilators, or so as not to subject the plants to cold draughts. Attention will be necessary in damping the benches and paths every morning. The sphagnum and the roots outside the pots and baskets will require frequent damping. especially Aërides, Phalsenopsis, Saccolabiums, and Vandas. Cattleyas and Leelias though rooting freely require very little water, the peat in which they are potted being of a kind that will admit of the water passing freely away. Odontoglossums should never be allowed to become dry, as they delight in a cool damp atmosphere. A light sprinkling overhead on fine mornings will be atmosphere. A light sprinkling overhead on fine mornings will be very beneficial to them, taking care that drip does not get into the young shoots; and as plenty of light is essential, wipe over the inside of the glass once a week with a sponge. If it be desirable to retard the flowering of Dendrobiums they should be placed in a greenhouse temperature and have very little water until they begin to grow, when they must be removed to a warm house, as any check will be followed by a stunted and frequently abortive growth. Cypripediums and Cymbidiums require a good supply of water at the roots. water at the roots.

TRADE CATALOGUES RECEIVED.

Ewing & Co., Eaton, Norwich.—Lists of Specialities.
V. Lemoine. Rue de L'Etang, Nancy, Meurthe-et-Moselle.—Catalogues of Bulbs and Miscellaneous Plants. Keynes & Co., The Nurseries, Salisbury .- List of New Dallias.

TO CORRESPONDENTS.

** All correspondence should be directed either to "The Editors" or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

ADDRESS (Confera).—Write to Vilmorin, Andrieux, et Cie., Quai de la Megisserie, Paris. France. (E. C.).—A letter posted to you to the address you supplied us with has been returned to us by the postal authorities.

PRUNING CLEMATISES (P. T. J.).—If the plants are grown in beds for producing low close masses of flowers they may be cut down pretty closely annually, giving the beds at the same time a libral dressing of manure and Iresh soil; but if grown on walls or trellises it is not advisable to cut the plants down, but they should be shortened to the bold buds that may be seen on the growths.

FILMY FERRS (Idem).—Such species as Todes superba, Trichomanes radicans. Hymenophyllum Wilsoni, and H. tunbridgense would possibly survive uninjured the low temperature you mention, but it would be fatal to the majority of species. We know several instances where Todeas were retained in unheated houses throughout last winter, and the plants are now in an extremely vigorous condition, thus proving that a higher temperature is not essential to their welfare. We should, however, advise you to protect your plants from frost if possible.

MILDEW ON CHRYSARTHEMUMS (A Lady).—The plants are frequently affected with mildew, when they become partially exhausted with blooming and by being crowded together in conservatories and other structures. As you deem sulphur unsightly you might try Ewing's mildew composition, which has been found efficacious by many gardeners.

which has been found efficacious by many gardeners.

ARALEA LEAVES FALLING (Mrs. M.).—It is the habit of Assless to cast a number of their leaves at this season of the year, but still it is very undesirable that the plants become seriously defoliated. Sodden soil on the one hand and excessive dryness of the roots on the other, contribute materially to the undue loss of foliage. So long as the soil feels pasty to the touch the plants do not need water, but immediately it crumbles when pressed with the fingers water should be applied so thoroughly as to penetrate every portion of the soil. A temperature of 40° by night and 46° by day without sun is quite sufficient with otherwise good attention for keeping the plants in good health.

Hoperuparature of the soil of the soil of the soil feels plants in good health.

the plants in good health.

HORTICULIVERLE STUDENTS (J. R. J.).—Several noblemen's and gentlemen's gardeners take pupils, but we doubt if your friends, "who have been brought up in a city business," would be considered eligible candidates; and further, private gardens are not suitable for preparing young men for engaging in commercial horticulture. A nursery training would be far more serviceable, and, indeed, is essential to gaining a knowledge of plant culture for the trade and public markets. Your young friends, without practical experience of plants and the plant trade, would run great risk by embarking their capital in the manner proposed, and the only mode that we can suggest is for you to apply to the leading nurserymen in reference to obtaining appointments for them on payment of a premium. Lectures on scientific botany are regularly delivered during the winter and spring months in the Royal Gardens, Kew, but we do not know whether they are attended by others than the students and employes of the establishment; you might ascertain by writing to Mr. Smith, the curator. Such lectures are not, we think, delivered at any other institution in or near London.

Aronna (W. C. E.).—From your describing the tree "as somewhat like

not, we think, delivered at any other institution in or near London.

ARONIA (W. C. S.).—From your describing the tree "as somewhat like a Hawthorn" we think it must be Crategus Aronia, which may be obtained under that name from nurserymen who deal largely in hardy shrube and trees. You say you cannot find it in nurserymen's catalogues, but if you axamine Veitch's, Osborn's, Wm. Paul's, Hogg & Robertson's, and Lee's lists you will find it in them all. There is also a Pyrus grandfolis, which is probably the tree referred to at Longlest as Aronia, but the latter name was rejected many years ago. The Pyrus is not so common in cultivation as the Crategus, but the name appears in the catalogue issued by Messrs. Osborn & Sons, Fulham, from whom no doubt you might procure it.

MANUAL SIDDEPURCHMEN OF LINE (Construx Georgies).—The following.

MAKING SUPERPHOSPHATE OF LIME (Country Gerdener).—The following extract from the "Gardeners' Year Book for 1880," which is now being distributed, will afford you the information you require:—Place 5 cwt. (or 13 bushels) of bones, on an earthen floor, surrounded by a rim of sahes; pour on as much water as the bones will suck up, and then pour on 2 cwt. of sulphuric acid; it will boil somewhat violently for a while; when this has subsided it will get tolerably solid, and the ashes and all may be shovelled up together, and will be fit for drilling in a day or two.

ROSES FROM FRANCE (A. J.).—You cannot do better than unpack them as you propose and lay their roots in soil in a cellar if the severe frost continues, but the soil must be fairly moist, and the roots must be well and firmly covered, and the cellar must be a cool one. Immediately the frost departs lay them carefully in a sheltered border outdoors for a time, and if severe weather recurs cover the stems and heads with straw. We should not plant them for at least two months, as if they are well laid in they will be safer than if planted where they cannot be protected.

Heating Greenhouse and Pir (A New Subscriber).—The greenhouse will be satisfactorly heated by two rows—i.e., a flow and return, of 4-inch pipes along the front just clear of the Vine border. The pit will require two rows of 4-inch pipes for top heat and two for bottom heat beneath the bed, which we should have on the side facing west, and 4 feet in width, leaving a pathway 2 feet in width at the back. The boiler will need to be fixed in the shed at the east end, the hot-water pipes being taken across the end of the greenhouse into the pit, along this at the back, across the south end, thru along the front above the bed, returning twice through the bed. being taken across the pathway below the floor at the door end and thence to the boiler. The greenhouse flow and return pipes may be taken as branches from those of the pit, having valves so fixed in the greenhouse and pt pipes that they may be heated separately or together. One of the improved saddle boilers

would be most suitable for your purpose. We cannot give an estimate of the cost. The best plan is to send a sketch of the proposed mode of heating to a horticultural builder and ask for an estimate.

PLANTS TO MARK THE LINES OF LAWN TENNIS (J. C.).—The plants most likely to succeed are Antennaria tomentos, Cerastium tomentosium, Poa trivialis argentea elegans, Dactylis glomerata variegate, all having white or variegated foliage, and stand as much cutting as grass. The bands or lines should be rather wide, and be trimmed occasionally to preserve their uniformity.

formity.

REMOVING MOSS FROM A LAWN (H. D. A.).—In the first place see that the ground is well drained; if not, drains should be made 6 or 7 yards apart, having proper falls and outlets, and should be 3 feet deep. It would be useless killing moss 8 inches thick, it must be removed; and as you are contemplating aitering the level of the lawn and doing away with some flower beds, we should have the ground deeply dug, burying the moss, and afterwards apply a good dressing of manure. Having made the surface even sow a mixture of lawn grass seed during moist weather in April, and after raking lightly roll well. The first mowing should be done with a scythe, and afterwards use the machine, rolling frequently.

REPOTTING EUPHORBIA JACQUINIÆFLORA (W. Hall).— It should be done in spring after the plants have flowered and been cut back, and when they have made fresh growths an inch or so in length remove most of the old soil and repot the plants in fresh compost in the same or a slightly larger pot. Herniaria glabra, Mentha Pulegium gibraltarica, and Alternanthera amoens cannot be raised from seed fit for planting in June; indeed they are not increased in that way but by cuttings.

LIME FOR VINE BORDER (M. J.).—Two bushels would be a sufficient quantity of fresh slacked lime to apply to a border 30 feet by 15 feet. It is necessary to apply it to both the inside and outside borders.

Heating Propagating Pit and Greenhouse (Kutte).—There is no necessity for side ventilation, the sides lights necessarily being more expensive than brick walls. The top ventilation is sufficient, having a light 2 feet wide to open the whole length of the house. You will need the piping shown in the sketch—viz., two pipes in each bed for bottom heat and four for top heat, presuming you to require the pit for growing Cucumbers in winter or early in the season, otherwise those at the sides are sufficient for the top heat necessary for propagating bedding plants, and for Cucumbers and Melons afterwards; in that case you may dispense with the pipes on the bed walls. The ventilation should be on the south side of the house; and a division would be an advantage, so to have one part in use for propagating, and the other could be used to encourage the speedy establishment of the plants after potting them off. A compartment 9 feet in length would be sufficiently large to propagate a great number of plants, and you may have the four pipes for top heat in that compartment, and the side ones in the other will be all that are necessary for top heat, along with those in the beds for bottom heat, which will be necessary only for the Cucumbers and Melons, unless you wish to use the beds for propagating purposes. The greenhouse will be satisfactorily heated by two rows of 4-inch pipes—i.e., a flow and return taken along the front and one end. The pipes for the pit should be 4 inches in diameter.

A inches in diameter.

PROTECTING ROSES (J. B.).—Wrap haybands—if not too late—round the stems of the standards, partly uneolling the top of the bands and twisting them loosely round the heads of the Roses and amongst the branches; further, wisps of hay, fern, or other loose light material placed in and around the lower part of each head and secured will be of great benefit. That portion of the Rose nearest its junction with the Briar is the most liable to be injured by the severity of the weather, and the Briar stems are also often injured during extreme frost. Dwarfs may be protected with the same material, in addition to the ground being well covered with manure; but if you have snow in your garden and heap it on the beds and around the Roses it will prove the best protection that you can apply. We are unable to answer your question relative to the National Rose Society. If you write to the Rev. H. H. D'Ombrain, Westwell Vicarage, Ashford, Kent, you will have our attention.

NAMES OF FRUITS (N. C. H. Q.).—You have put no numbers or other

NAMES OF FRUITS (N. C. H. O.).—You have put no numbers or other distinctive marks on your Apples, and it is therefore impossible for us to refer to them.

NAMES OF PLANTS (F. G.).—1, Widdringtonia cupressoides; 2, Retinospora filicoides; 3, R. obtusa aurea; 4, Kalmia rubra.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

HOUSE AND SHED FEEDING OF SHEEP.

AT various times when the management and feeding of different breeds of sheep have been under consideration in this Journal, we have on several occasions hinted our intention of treating the house feeding of sheep in a separate article, and we now propose to make good our intention. We think we have chosen a time of year for that purpose well suited for the consideration of the subject, because house feeding is peculiarly adapted for the winter season, and in fact it cannot be justified as a method of management for sheep stock during the summer months. There are various reasons which will justify the home farmer in the house feeding of sheep, more especially where pasture and park lands prevail with but a small portion of arable land attached; and whenever the arable land is found of a heavy and tenacious character it is of the utmost importance that the animals should have a dry comfortable lair and protection from the frost and storms of the winter months. We feel assured that this mode of

management of the sheep stock of the home farm will commend itself to the noblemen and gentlemen as proprietors of valuable domains in various districts of the kingdom, for the system will in nowise interfere with summer feeding of sheep on the park and pasture lands, where they are held to be by many quite ornamental as well as profitable for consuming the grass produce. We find many gentlemen whose pride and pleasure it is to possess a well-bred flock of a class of stock adapted to the soil and climate whereon they are kept. It frequently happens, too, that proprietors of estates have a fancy for certain breeds of stock, it may be Downs, Cotswolds, Leicesters, or horned Dorsets. In either case it falls to the lot of the home farmer to carefully rear and feed the animals which may best suit the estate, to be fed for profit, or used for furnishing meat for the establishment. It may also be required of him to rear and care for a breed of animals intended for exhibition at the metropolitan and other stock exhibitions; and with these and other objects in view it will be our task and endeavour to lay before our readers the means whereby these advantages can be obtained. We shall not only give our own opinions based upon a long experience, during which we have obtained prizes for sheep and lambs, and the opportunities we have had for many years of visiting the best managed estates where house feeding, &c., of sheep has been carried out with great care and with varied success, but under widely different circumstances of soil and climate, in sheds, houses, and apartments of widely different and varying construction as accommodation for the animals, as well as the saving of manure in the most economical form, having also due regard to the health and profitable feeding of the stock.

Having prefaced our subject with the foregoing observations we proceed to give illustrations of the methods adopted for house and shed feeding by those gentlemen and farmers who have taken great interest in carrying out experiments which were not only interesting to themselves, but when properly considered must be accepted as exceedingly useful in connection with the science and practice of agriculture. We will first make some allusion to the plan of producing house lambs, which has always been considered as one of the greatest delicacies and luxuries available at Christmas. We would remark that although the taste for early lamb is now as prevalent as ever amongst epicures, yet the demand for this meat at that particular period has decreased, and the system of house feeding has nearly fallen into disuse as formerly carried out; nevertheless a short description of it may not be without some point in connection with house feeding of stock-It was usual for some farmers forty and fifty years ago living in the counties bordering on the metropolis to purchase the horned Dorset or Somerset ewes which were the earliest to lamb-viz., at the end of September and the early half of October. The ewes selected were required to be of the purest breed, of the largest size and milking capacity, and also with white noses, for animals showing any black either on the nose or eyelids were rejected The colour of the flesh of house lambs when butchered is a matter which in a great measure governs their value, and those which can be warranted to die fair in colour always obtain the highest price and in particular seasons about Christmas time the best house suckled lambs have been known to realise from £3 to £5 each, although not weighing more than 8 lbs. per quarter. These lambs were never allowed to run with the dam in the usual way, but were kept in a house, and as much as possible in the dark, the object being to induce sleep. The ewes were allowed to feed in a piece of land near to the homestead of dry pasture and were fed with the best roots which were in season, but nothing being better than cabbage, together with a liberal allowance of oilcake, pollard, ground oats, in fact anything which will produce milk of the best quality, the quantity being insured by the horned ewes, the most milky of any breed we have ever met with. The lambs were kept in welllittered pens, and the ewes driven into the house to suckle them three times a day, and to lie with them during the night. This process entailed considerable labour and nicety of management, but the prices at which the lambs were sold proved profitable to those who understood the business. The public taste has since altered

very much, and but few now attempt the suckling of house lamba seeing that capital lambs can now be had at Christmas time in the open air, we having often sold ten or twenty lambs at Christmas, the ewes having lived principally upon Italian rye grass and oilcake, which realised prices varying from 40s. to 50s. each. There is, however, a plan of shed feeding which is still kept up whereby the ewes and lambs are fed and accommodated in sheds and yards, and the lambs allowed to run through a lamb gate and feed separately and apart from the ewes. These lambs are often so quickly made and prove so fat and delicate that they are almost equal to lambs reared by the old style of suckling. It answers well with Down lambs, for they are by this means enabled to appear in the markets at Easter, heavier and of better quality than can be made in the open fields, even upon the driest soils, when they are properly provided for in the sheds. In proof of this we have taken particular notice during a period of nearly fifty years, and observed at the different exhibitions of fat lambs for prizes in the southern counties, that the shed-fed lambs have always obtained the prize over those fed in the field, and in consequence for many years they have been excluded from the competition with stock fed in the open air, and when shown it has been in a class set apart for that

purpose.

The construction of sheds or pens best adapted for feeding sheep in will be the next matter for consideration. This is of the greatest consequence for various reasons, but more particularly now that the animals are prone to suffer from the epidemic lariy now that the animals are prone to surfer from the spotemic lameness and foot rot. We frequently hear the home farmer say, Why should sheep be housed, as they have generally grown fat whilst in the fields if carefully fed? We concede this without hesitation; but our point is that they eat less food—a matter of no small importance when roots, &c., the produce of the farm, are scarce, as it is admitted by all that warmth, comfort, and with the continuous services and the services and the services are services. quietude are large equivalents for food. As we do not allow our fatting bullocks to lie out in the pastures day and night eating roots, cake, &c., in winterly weather, a reasonable question to ask is, Why should we not feed our sheep in the house as well as our cattle? The only answer is, Because it is not customary to do so. Which will return most profit? is not a question so easily answered, and the matter of fatting "bullocks versus sheep" under the like conditions will furnish us with an important subject in these columns at a future time. Upon the home farm we may not be willing to house all the sheep, therefore those which are required as store animals may be fed in the open field, and half or one-third of the root crop pulled and used under cover for both beast and sheep; the rest of the roots being fed upon the land in addition, will always insure a full crop of with oilcake, &c. straw or haulm in the succeeding crops, whether it be grain or pulse, and the land will be left in good condition, whilst the portion used in house feeding will have served its purpose for feeding fatting animals, and have left behind, under judicious management, a very valuable addition to the manure of the farm. Although this question may be worth consideration by the tenant farmer, it has a special claim on the attention of the home farmer, because sheep will be constantly required of good quality for killing and use at the establishment of the proprietors of estates, independently of those which may be kept and sold for profit.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour .- Horses can now only be employed upon the land in consequence of the changeable weather and frost; still the wheat sowing, of which there is more than the usual quantity at this period, must be done at every favourable opportunity, and especially is it desirable that the land should be sown or drilled as fast as it is ploughed. If the land is left over for a day or two with the view of sowing a whole field at once, rain or frost will interfere with the work, and it may be months before a fair seed time can be obtained. We have occasionally cautioned the home farmer against sowing wheat the produce of the last harvest as being bad policy, in consequence of the grain not having ripened in a natural way by the influence of the sun. The corn, during progress towards maturity, was killed by adverse weather; and we considered that the grain, being so thin and defective, would not in many cases vegetate at all, and if it did it must prove a very markly plant and restrictions. weakly plant and quite unable in some soils to maintain itself during the alternations of winter weather. We now find that our caution is justified, because we know cases in which the corn was early sown; and, although some of the seed did vegetate, yet it has died in the land in some instances, for, although it had power to vegetate, the mother grain could not nourish the young plant well enough to enable it to obtain a roothold upon the soil. It is therefore a serious consideration for the home farmer as to providing seed for the land not yet sown. We therefore recommend the seeding with some of the beautiful samples of foreign wheat which are now selling in all the markets, or otherwise to obtain wheat of the previous year's home growth if the sort required can be found. We have acted upon what we have recommended, and sown only wheat the produce of the harvest of 1878. There is also a great complaining amongst farmers that the rye and vetches have not vegetated in many instances; this, too, is no doubt in consequence

of the corn not having ripened and matured at harvest time. This ! will be a serious matter upon some hill farms in the spring of the year in a season like the present, when there is not half a crop of roots upon many farms, and especially on farms without irrigated meadows. The crops of Italian rye grass will in such a case be of more than usual value, and the ground should receive 2 cwt. per acre of nitrate of soda as soon as the weather is open, in order

to forward the crop for feeding at the earliest period.

Hand Labour.—This will now be required in a variety of work, such as making out water furrows on the newly sown wheat land, filling dung carts, and spreading upon the clovers or meadow land after being laid out; also the same work connected with chalking the land, and also breaking the lumps of chalk, in order that it may be reduced by the action of frost and the more quickly become incorporated with the soil. Earth which has been carted on to the soft meadow land should be spread so that the first rains which occur may wash it into the turf. The shepherd will now be busy, as all his stock will for the most part, particularly the ewest be cared for in the lambing yard and sheds. The fatting sheep in the field with ordinary attention will do well during dry frosty weather, but should receive a smaller quantity of root food, with a larger quantity of hay and cake or corn, the latter given as meal or crushed fine and mixed with cut roots. The young cattle in the yards and sheds will require something besides straw and roots, for in many cases the roots cannot be spared for them, being so nor in many cases the roots cannot be spared for them, being so much required for fatting cattle and sheep, and even these should have a diminished quantity, roots being so scarce this year. The straw in many cases this year does not possess much feeding quality. If, however, it has been harvested fairly well and is not mouldy we may expect it to be nutritious, because the straw did not ripen as usual, but was killed as it were in the green state, and the analysis of straw cut early and in an unripe state stands high for nutrition, so that we may expect the straw of this year's growth to be of fair feeding value, although often found of a dark colour. Straw should always be spiced at slaking or when chaffing, as it makes it more attractive to the animals. In the dairy it is important in the winter months to keep up the colour and quality of the butter, and when the cows are eating vegetable food it should be cabbage or kohl rabi in preference, with sweet hay and bran or maize meal mixed with them, and thin wheat of the present year's growth will answer with cotton cake in admixture. Apart from feeding it is a good plan to purchase a well-bred Guernsey cow just calved; her milk being so rich and high coloured will improve the butter considerably, for it is no use to expect butter of the best colour from root-feeding in winter unless the cows are all of the Channel Island breed. The feeding of horses for work on the farm is now of some consequence, for we cannot expect them to do so well when fed only on dry food; they should therefore have about 6 or 8 lbs. daily of carrots or Swedes grated and mixed with their chaff. The feeding of pigs at this time of year is usually with milk and meal; but we have often when milk has not been available, for the weaning calves sometimes require it, used carrots or mangold pulped, the meal being mixed with it, and the meal gradually increased until the month before slaughter, then we use all meal mixed as usual.

SOUTH AFRICAN GUANO CAVES.—Several deposits of valuable guano exist in different parts of the Cape Colony, the best-known being those in the Bird Island, in Algoa Bay, and on the mainland adjoining Saldanha Bay. These are chiefly noted for their large per-centage of phosphates. A new store of guano of very different characteristics has lately been discovered in a series of caves near Montagu, Robertson Division, about 100 miles east of Cape Town, where it is estimated that about 400 tons are available for immediate working. The guano is described as being a light brown powdery mass, in which a number of solid nodules occur. It is powdery mass, in which a number of solid nodules occur. It is perfectly odourless, giving out no trace of ammonia. The latter substance, however, is evolved at once if a small quantity of the guano be heated with burnt lime. The solid nodules contained in the guano are of different size, varying from one-tenth of an inch to an inch in diameter. They consist chiefly of ammonia-salts and of soluble phosphates. An analysis of the guano shows that it contains 68 per cent. of ammonia compounds, 16 per cent. of phosphates, and 2 per cent. of nitrogen. In the same caves are considerable quantities of salts, forming a crystalline mass, containing 33 per cent. of phosphoric said 11 per cent. of subhuric considerable quantities of salts, forming a crystalline mass, containing 33 per cent. of phosphoric acid, 11 per cent. of sulphuric acid, 15 per cent. of nitric acid, 19 per cent. of potash, and 7 per cent. of ammonia. This salt, though too acid for use as manure alone, is of great value as a material for making artificial manure, and, if mixed with a proper proportion of potash or carbonate of ammonia, would make a most valuable fertilising agent. The land containing these caves was lately offered for sale by the Cape Government .- (Colonies and India.)

WHAT IS THE BEST VARIETY OF FOWL?

"What fowl would you advise me to keep? I am thinking I should like to keep some, and you know better than I do what are best."

to the writer, and judging by answers to correspondents almost a standing dish to the editor of a poultry chronicle. I always answer my queries with another, "What do you want the fowls answer my queries with another, "What do you want the fowls for? and afterwards, what sort of places have you to keep them in?" "Oh," says my friend, "I have a good yard, and there is the croft they can run in, and I can easily knock up a house for them in one corner, and I should like a few nice fowls." "Well, do you want them to show, or for market, or for ornament, or what? Because if the former you must fix upon some pure breed. need not at first attempt to buy prizetakers, but procure some fair stock, and when you are well accustomed to them you can begin stock, and when you are well accustomed to them you can begin in earnest with something better; and you have always one advantage in breeding pure stock when of sterling merit—a certain proportion of your birds will realise what may be called fancy prices as prizetakers or stock birds. Your early pullets you can always dispose of in the autumn at satisfactory rates, and your worst are worth as much for market as mongrels to say the very

"Oh no," shaking his head, "I don't want to bother with prize birds; I should never get a prize if I showed and nobody would give me more than killing price for them. I merely want some good fowls. I want some good layers, not those that are always sitting, but yet I should like to rear a hatch or two of chickens in the year; and I should like some good early chickens for the the year; and I should like some good early chickens for the table, but not to have a great amount of trouble over rearing them, and the hens must not be flying over everywhere because of the neighbours' gardens; and I don't want your poor little things, but some good-sized, hardy, useful fowls, that will lay plenty of eggs when they are scarce and dear; and I don't want them if we have any to kill to be long-legged birds without any west on their beauty. Now what had I better have? meat on their breasts. Now what had I better have?"

Our friend wants something not far removed from perfection, but this is not yet attained by any pure breed that I am acquainted but this is not yet attained by any pure breed that I am acquainted with. We must have a cross to get all these good qualities, and of all the cross-breeds I know, none please me so well as the Dorking-Brahma or Dorking-Cochin. To breed these rightly obtain, if possible, an old-fashioned, short-legged, heavy-bodied dark Dorking cockerel (not the stilted cockerel of our show pens), and from three to six good-sized broad young Brahmas or Partridge Cochins. Their early-hatched pullets will lay in the autumn, and with care through the winter; they are good sitters and careful mothers, while for table unequalled, having the grand breast and white flesh of the Dorking, with a richness, especially in the Brahma cross, that in my opinion the pure Dorking is deficient in. The chickens are very hardy, and are ready for table in a very short time; they are easily kept within bounds, and are an ornament to any poultry yard. I have several by no means full-feathered from 13 lbs. to 15 lbs. per couple cockerel and pullet. I supplied a friend of mine with birds such as I describe about two years ago, Dorking cock and Partridge Cochin hens. Some of his pullets of last year began to lay last autumn, and have continued almost without intermission up to the end of last month, even during the greater portion of their moult. One who had a hatch of chickens in June began to lay about nine days after hatching, and continued all the time her chickens were with her, and up to the time I state.

The advantage of thus pairing two pure breeds is incalculably greater than merely turning a pure cock among a lot of mongrels. The plan is, keep the pure breeds and rear from them alone; kill the young cocks as soon as ready or convenient; sell off in early autumn the year-old hens, having plenty of early hatched pullets to take their place; or some of the year-olds may be kept another season, though time is sure to be lost during moult, but on no account be tempted to breed from them; or if you do, kill the progeny off for the pot, and do not encumber your yard with them. Do not be tempted to buy cross-bred fowls or eggs without you know they have been raised according to my instructions. great portion of the so-called cross-breeds are worthless and sure to disappoint, but with the cross I describe satisfactory results may be anticipated.

The cross between the Black Spanish and Black Cochin makes a very useful fowl only second to the above; indeed with a little selection I consider, though I hardly dare say it, that they are scarcely to be distinguished from the Langshan. Either of these crosses are really first-rate, and combine in themselves almost

every valuable property of the poultry yard.

Some persons, however, desirous of keeping fowls, have no grass run, only a small pen or yard. For their benefit I will narrate the following experience of successful poultry keeping under exceptional circumstances, and for the truth of which I vouch.

I sold a friend of mine six or seven Brahma hens and a cock; he placed them in a corner of his garden wired in, the space being about 4 yards by 5; with a few old boxes a roosting place was made, and also some nesting places. They laid well, reared chickens, and he kept adding to his stock till he had altogether ten or twelve hens. He changed his Brahma cock for a Dorking, sold the eggs from the cross in the neighbourhood with the bes results, reared some of the chickens himself, kept a cross-bred te to keep some, and you know better than I do what hen or two, and at last quite six years after he commenced keep-Such is by no means an infrequent query propounded ing fowls he sold the whole of his stock including the hens he first

purchased, having lost only one bird by death or otherwise during the whole of the time. The birds were never let out, but the ground was sloped so as to drain naturally, and fine ashes every few days were thrown over it; the bird were well supplied with water, had all the kitchen scraps, an abundance of green vegetables, and a minimum allowance of corn.—NORTH SHROPSHIRE.

BIRMINGHAM POULTRY SHOW.

(Continued from page 454.)

was again first, this year with a nice pair of Silvers, good in ground colour and small; second a very good pair of Golden; in lacing we almost preferred them to the first pair, but they are far larger. White Rose-combed were better than me handless. for some years; we have before noticed the cup pair, they are little gems. Second very good in combs, a little red in lobes. Black Rose-combed numbered eleven pens. First the little pair which won at the Crystal Palace; in the second pen a pretty very young cockerel. The Any other variety Bantam class was very Single-combed Cuckoos were first, and White Japanese second. In the Selling class were a pair of Cuckoos with rose combs, too cloudy, but otherwise pretty, entered as "Old English

[We regret that the portion of the report referring to the Gams classes was lost in transit through the post.]

PIGRONS

These were a grand collection—indeed, we do not remember ever to have seen them so fine at Bingley Hall. The quality of the Carriers was such as has never before been seen at the great midland counties Show, and the adult classes were undoubtedly very well judged indeed. In the young classes very neat birds very well judged indeed. In the young classes very heat birds were shown, but the awards were not well selected, the Judge evidently going in for small neat birds and leaving out those that most undoubtedly will make fine specimens in time. Of Pouters a large collection was shown. Some of the awards very much surprised many fanciers who know this class well; but taking the judging through there was not so very much cause for complaint, every one of the winning birds being of remarkably good quality. In Tumblers a splendid lot far outstrips all previous years at Ripoley Hall. Every of the Almonds must have puryled ears at Bingley Hall. Four of the Almonds must have puzzled years at Bingley Hall. Four of the Almonds must have puzzled the Judge as to which to select. The variety Short-faces were equally as good of their kind as the Almonds, the awards being particularly good. Balds and Beards, Short-faced, also show great improvement in quality, and a matter of choice amongst the three winners as to which was the best; but we are glad to state as our opinion that there was no cause for grumbling in the actual awards. Muffed Tumblers were a magnificent class and also well judged, but we are sorry to say that many good birds must have been passed over in consequence of their owners attempting artificial improvement, thereby causing their birds to lose the chance they otherwise would have had. Barbs as a class were only poor; they otherwise would have had. Barbs as a class were only poor; the cup bird, however, was remarkably good. The young class also poor, and several showed unmistakeable signs of too old-fashioned an appearance. The Fantails were a good class, and the awards exceedingly well considered. We are pleased to be able to congratulate the Judge on having selected the three best out of so many good ones. The Trumpeters were the best we have ever seen at Birmingham. We are glad to see this, as this is one of the handsomest varieties of Toys of which we are possessed. Jacobins were good classes; the cupwinner, a Yellow, as near perfection as we could wish to see. The awards in both classes were very good. Turbits were very good, but we could scarcely agree with all the awards. We could not understand how a Blue, being chequered in body and having Kite bars, should with these defects win a first prize. Although no great lover of the Antwerps, we could not but admire so grand a display as was here brought out. We were sorry to see them placed in such a position as to make it impossible for any judge to give correct position as to make it impossible for any judge to give correct decisions, the birds being placed nearly on a level with the floor. decisions, the birds being placed nearly on a level with the floor. It was hard work for even visitors to inspect the birds. The Dragoon classes were also splendid, but placed in a bad light for the Judges to discover their points. Exhibitors have a right to expect that their birds are placed in proper positions in justice to themselves, their exhibits, and also the Judges. The Short-faced frilled varieties, also Any other variety, contained many beautiful specimens; indeed, it was a mere lottery in these classes as to which would win, there being so many good birds shown in them. shown in them.

WATFORD POULTRY SHOW.

THE annual Exhibition of poultry in connection with the West Herts Agricultural Society was held on Monday and Tuesday in the large Agricultural Hall. The Dorkings and Turkeys were the best classes in the Show, but the Brahmas included several noted winners, and the Dark birds were very good. The Light Brahmas were also good, but we thought the cup should have gone to the second-prize pen (Mr. Breeze's) rather than the first. The Ducks

were fair, the Geese good. Among the Bantams we preferred Mr. Leno's Sebrights to the Japanese that won the first honours. The pen of Dorkings, belonging to the Rev. E. Bartrum, that won the Dorking cup and the champion cup for the best pen were acknowledged to deserve their position, but the second-prize birds were also good, and the Silver-Grey class also contained a very fine pen. There was an excellent collection of *Pigeons*, which, placed in a good light, excited much interest. Mr. W. J. Nichol was Judge, and seemed to give general satisfaction.

was Judge, and seemed to give general satisfaction.

VARIETIES.

It is now high time for those who wish to have early chickens to put up their breeding pens. We hope in an early number to give some hints on judicious mating. It often happens that expensive pens are bought at shows and put together indiscriminately, the result being failure, when the expenditure of far less money judiciously laid out might command success.

· In our first article on the "Any other variety class" we dealt with Buff Polish. Curiously enough, within a week we observed one of the most beautiful pairs of the breed we had ever seen taking first prize at Birmingham in the said class. There were others far less meritorious, but by no means despicable specimens of the breed in the class, at a moderate price, so would be fanciers of it might now have a chance of a pen to begin with.

— Polish are an exceedingly long-lived breed, and seem to feather well to the end of their days. The famous white-crested hen which Mr. Darby so long and so often showed successfully must have been at least ten years old the last time she was at the Palace, and, if we mistook not, the first-prize hen last week at Birmingham was none other than "Patty," which for many years won in the hands of the late Mr. Norwood.

—— SALES at Birmingham were by no means behind former years, in spite of the bad times. In Dorkings Mr. Burnell's Dark cock went for £18 7s. 6d.; Mrs. Lagan's White cockerel for £10, the same lady's White pullet for £5, and Miss Milward's Dark cockerel for £8. In Brahmas Mr. Kendrick's Dark cock (second) fetched £20, Mr. Ansdell's cup oockerel fifty guineas, Mr. Percival's Light Brahma cock £21, Mr. Morris's Light cock fifteen guineas. In Cochina Mr. Swindell's cup Buff cockerel realised 220, Mr. Clatworthy's Buff hen twelve guineas, Mr. Percival's White cock £12 10s., Mr. Chase's ditto £25, and the same exhibitor's unnoticed cockerel ten guineas. In Hamburghs, too, some high figures were reached, a Silver-spangled cockerel, we believe, being sold for £21.

- WE understand that the Committee of the Poultry Club — We understand that the Committee of the Politry Club have decided to give aid to shows which adopt the rules of the Club. At present it is to be in the form of the guaranteeing of prizes for classes which might otherwise fall through. The Committee of the forthcoming Wolverhampton and Shrewsbury Shows have applied for this aid, and in each case the Club guarantees the prizes of six classes to the amount of £8 10s. in each class. Of course, should the entries be large little or nothing will represent for the Club to pay, should they be small the prowill remain for the Club to pay; should they be small the promoters of the shows will not suffer.

— WE wish the rule against divided baskets could be relaxed at Birmingham. Surely it would cause little trouble if birds of the same breed might be sent in the same basket properly partitioned. We saw with much regret that all Mrs. Forsyth Grant's birds had in accordance with this stringent rule been refused admission, and could not fail to sympathies with the recretion of having sent a number of rear from Montrose to vexation of having sent a number of pens from Montrose to Birmingham and back for nothing.—C.

A CORRESPONDENT of the Agricultural Gazette writes as follows relative to rooks and newly sown crops-Let me strongly reccommend the following plan which I have practised for the last five years. Get a sentry-box sort of structure made, costing from 7s. to 9s. As soon as your corn is sown, place it in the middle of your field and then leave it. No crows will venture near it, at all events for some time—probably not at all. If, however, some, more adventurous than others, should after a while begin to attack your crop, place yourself in the box, and on their alighting fire a gun out of the box, but without showing yourself. They will never trouble you again so long as your crop is in any danger. When done with for the wheat crop remove it to your Swedes (if you do not pie them), to which very serious damage is often done; it is equally efficacious there. It eats nothing, it does not come at pay night for wages, and will efficiently protect from 35 to 45 acres, if they are fairly level. Though living near several immense rookeries I have not spent Is. in corn tenting, and have not had the least injury done to crops or Swedes since adopting the—Sentry-box.

—— THE total harvests of Europe are computed by the Bulletin des Halles at 984 million bushels in lieu of 1177 millions, the average yield, so that 248 million bushels will be required, of which America can furnish 165 millions.

— The New York Sus says, a larger number of tubs or packages of butter changed hands in that market the second week in September than ever before. The exact number of packages sold is not known, but in round numbers it is not less than 175,000. A prominent firm in Warren Street sold 10,000 packages in one transaction, and the amount of money involved was \$65,000. The money paid to American shippers of butter in the course of the week's business cannot fall short of \$500,000. This butter is bought by agents for dealers in England and on the continent.

— The fifth annual sale is announced of poultry from the celebrated yard of Lady Gwydyr. The sale takes place on the 17th inst., when three hundred birds of the different varieties of Brahmas and Black and White Cochins will be disposed of at the widely famed establishment of Stoke Park.

— The gentleman who reported upon the Dark Brahmas for us at Birmingham asks us to mention that Mr. Lingwood's third-prize cockerel there was not, as he at first thought, the second-prize Palace cockerel, but the unnoticed Palace cockerel of the same owner.

— WE learn that splendid collections of roots are exhibited at the Smithfield Cattle Show by Messrs. Sutton & Sons, Carter and Co., Webb & Sons, and other contributors, including a fine collection grown by the aid of Amies' manure; but as the authorities of the Show failed to send us tickets we are unable to refer more fully to these and other exhibits.

In any future war in Europe not only the heliograph and the electric wire will be brought more fully than ever into play, but Carrier Pigeons, no doubt, will also be very largely used, espacially when cities are besieged. It is therefore unsatisfactory to learn that a dispute is actually going on among judges of these birds as to whether a contemplated show had better take place at Paris or Rheims. If the birds were properly trained there ought surely to be no difficulty on this head; and if it be true that the Belgian Pigeons are generally taught only to fly in a south-westerly direction, and cannot be relied upon to go due south—as from Rheims to Marseilles—the sooner such a system of instruction is abandoned the better. At any rate, it would be well if English owners were to adopt a plan of teaching which would render it a matter of indifference to them whether the Pigeons were needed to fly to the north or the east. If Carriers are to be of any value they must be able to go in any given line, or it will not be difficult for, say, the besiegers of a town to take good care that no birds ever leave the place invested.—(Daily Telegraph.)

HOW LONG DO BEES LIVE?

WORKING bees are meant for queens, and drones are different creatures, and both are treated differently in their cells, and in life, and at death. Working bees live nine months. Bees born in August and fairly treated live till May. Of this fact we have had ample evidence in hives that bred no bees between these months, and in hives that had drone-breeding queens. Given a good hatch of brood in a good hive in the month of August or September it were easy to tell how long that hive would live if no more brood were hatched in it. It would gradually dwindle and become weaker in numbers till the last hatch of brood reached the allotted span of life—viz., nine months, and then "go out." During the last few years statements have been made by various writers and teachers touching the length of the life of bees, which are misleading. Many statements could be quoted, let one suffice. "I must remind you that it has been ascertained that no worker bee lives longer than five months at any period of the year, and in the height of the busy season their existence is much shorter." This quotation is made from a recent lecture pretty full of good common sense and practical teaching. If working bees live no longer than five months it would be a difficult matter for British and American bee-masters to keep their stocks alve during the shortest of winters.

For the comfort and encouragement of all it should be well known that working bees live nine months.

During the spring of the present year, in April, I found that one of my best hives had a drone-breeding queen all winter, and guessing that the youngest working bees in it were about eight months old I gave it a fertile queen and fed it well. The result was that three patches of brood (working bees) were hatched before the old bees died. Thus the hive was saved and did as well as the rest of my hives. It is well known that the loss of bee life in summer is very great, but who can tell whether the loss is caused by natural death or by accident? If men or bees expose themselves to risk of life and are cut down it cannot truly be said that they reached the span of life and died natural deaths. The instincts of bees, their care for their young and their industrial habits, prompt them to leave home often during unsettled weather. On their way to and from distant pasturage they are often caught and destroyed by storms. They perish on the altar of their own industry by thousands and hundreds of thousands. But is this natural death? On high authority it is said that some "men shall not live out half their days," and it may be safely asserted that many and most bees are lost before they have spent half their days. In good seasons and in favourable weather the effective forces of hives are not lost rapidly—nay, rather they multiply rapidly and swarm frequently. Some seasons hives are brought home from the moors having lost eight-tenths of their bees in three weeks, and some seasons hives are brought home well filled with bees. We have known 8 and 10 lbs, of bees taken from hives after seasons of hard work on the moors, and in other years we have known hives of equal size and strength return with less than 2 lbs, of bees in each hive. In one season the bees were killed or lost by weather or accident; in the other they were not so destroyed.

Are the bees whose lives are cut short in summer, killed by hard work or by accident? This is the question—the point of consideration which we wish to leave open for the opinion of others. If asked for my own opinion I would say, "death by misadventure." Of all bees queens are the hardest workers and do the hardest work, but they are never exposed to the hardships of outdoor labour or the accidents of weather. Queens come to their end by natural decay, generally speaking, at the age of four years. Working bees, let me say once more, come to their end and die natural deaths at the age of nine months or thereabouts. Drones are not allowed to live out half their days. Some are killed in infancy, and some are permitted to arrive at manhood before they meet their fate.—A. Pettigrew.

COTTAGE BEE-KEEPING .- No. 1.

It is now many years since a course of direct instruction to cottage bee-keepers has found a place in this Journal. Since then so great a stride has taken place in our knowledge of bees, and such great improvement in their management, that it seems only fair and reasonable that our humbler neighbours should have the benefit of them. I purpose, therefore, during the winter months to write a series of papers with the above heading, in the hope of re-awakening an interest in this branch of domestic economy (as it may fairly be called), and helping our cottage friends to make bee-keeping a success.

The last year has been so fatal to bees everywhere, in Ireland and Scotland as well as in England, that a general discouragement prevails among cottage bee-keepers. Many have lost every hive they possessed, and not a few, looking back upon the ill luck that has attended their management of bees for several years back, seem in despair, and feel inclined to relinquish bee-keeping. What if our farmers generally, who have had too much reason to complain of the bad times, were to resolve to act in like fashion? We should soon be in difficulties for the saving of dear life, famine would next winter be at our doors. But I cannot see that my farmer neighbours are taking less pains with their grain-sowing or dairy management than in former years for all the heavy losses they have sustained. They are taking care to supply their lands with manure, and their flocks and herds with good roots and hay, in faith and hope of better times. Why should the bee-keeper be less hopeful, or allow himself to give less attention to his bees? If indeed ill luck has visited him and nothing worse he has only himself to blame. Ill luck is usually but another word for utter neglect and carelessness. Why did his bees die? Why did he let the summer and autumn pass, and take no pains to help his bees by feeding them as he ought to have done, and as he fed his other live stock?

I begin, then, with this piece of advice to all intending beekeepers. Resolve from the first that you will not keep bees at haphazard, and do not expect them to pay if you take no trouble about them. Make up your mind to fail sooner or later if you will not help them with sufficient food to carry them through the winter and early spring after a bad season such as that we have just passed through. A very little trouble and a trifling deduction from the profits of a successful season wil! be sufficient to save your bees from destruction, and to guarantee you a super-

abundant harvest of honey at no distant time, more than sufficient abundant narvest or noney at no distant time, more than summent to recoup you a hundred per cent. on your outlay. Just imagine the vexation of many a bee-keeper next summer, when, as is probable, if it should turn out a propitious season, he sees his more careful neighbours' bees yielding hundredweights of golden honey, himself being out in the cold, and having nothing to show but a beggarly array of empty and decaying hives. "Feed me well," then, is a fundamental rule in keeping bees. Not less important and essential to success is the other half of the verse, "Keep me clean." How to feed I do not stop now to show. That will come presently, as also how to keep bees clean. I will only say here with regard to the latter, that the intending bee-keeper must make up his mind to attend to this as a matter of quite equal necessity. Hundreds of hives perish every winter for of a little regard to their healthy preservation. Damp, mildew, imperfect ventilation, poisonous exhalations arising from external or internal decay or death, are fruitful causes of instantaneous outbreaks of disease inside a multitude of stocks every winter. Accumulations of dead bees on the floor-boards, and entrances choked up by these or other things, are the direct causes of dysentery and ruin, and most likely of foul brood, within a hive. fore, whoever purposes to commence or recommence bee-keeping must make up his mind to give attention to these things. Let a new era begin, and all the old carelessness be for ever done away. Then there is some hope of success, and a golden time will come

These two points on which I lay such stress at the very outset of my papers imply, of course, that the cottage bee-keeper intends to take as much care of his bees as of his potatoes or of his cabbages. Talk of potatoes indeed in comparison of bee-keeping, which in these days has on the whole proved the most profitable? Which in these days has on the whole proved the most profitable? Numbers of cottagers this year have taken up actually a less quantity of potatoes than they put into the ground in the seed time. Estimate the cost of labour, and the rent of the ground, and the original value of the seed itself, and balance this with the losses of any bee-keeper in the neighbourhood, and which of the true has recent to the profit when the disappointment? I will the two has reason to cry most over his disappointment? I will take my own case. I have eleven hives which have given me no honey this year. They have cost me two hundredweight of sugar valued at £2 10s. The eleven stocks I consider are now worth at least 80s. a-piece, taking no account of the hives them-They will probably be worth a great deal more in the serves. They will probably be worth a great deal more in the spring. This time last year they were worth 10s. a-piece less. So that I have actually gained £3 on the value of the stock after deducting for the cost of food. What potato grower can show a proportionate increase in the profits of his root ventures this year? But if I had let my bees die out for want of that £2 10s. worth of sugar I should have found myself £13 poorer than I am now; and if I chose to carry on bee-keeping on the same scale I should have to pay as much again for them next year, not to speak of the honey profits I may not unreasonably expect to get in the good time coming. A greater goose than the "penny wise" starver of his bees could hardly be found.

wise starver or ins bees could hardly be found.

When will our cottagers open their eyes, and see what possibilities of improving their small incomes lie at hand and within their grasp? I and others have lectured, and written, and experimented before cottagers in various parts of England, but I can scarcely call to mind a single instance where a permanent success has followed the lessons given. There has been plenty of temporary interest shown in the subject, and not a few have been induced to keep hees for a time but with very rare according. induced to keep bees for a time, but with very rare exceptions failure has been the result, and for no other reason than the want failure has been the result, and for no other reason than the want of continued attention and sufficient care of the new property they have acquired. Not in any case that I can recollect has the profit been anything like what it ought to have been. It has now come to this point with myself, that I have ceased to go out of my way to induce any of my poorer neighbours to keep bees, simply because I am afraid they will only lose the outlay which is necessary for them to make, and consider me as the cause of their disappointment and loss of money.

cause of their disappointment and loss of money.

For all that cottagers will continue here and there to keep bees. In some parts of England they are more intelligent than in others. It is for such I write these remarks, in the hope that they will make a note of them and begin in earnest to mend their ways.— B. & W.

OUR LETTER BOX.

OUR LETTER BOX.

CANDY CARES FOR BEES (Syleanus).—The following is Mr. Raitt's recipe for making the cakes you require: —Boll in a common pot as much sugar as may be required, with as little water as will melt it—say half a teacupful to each pound of sugar. Keep stirring briskly for ten minutes or so; then try few drops on a spoon, holding it in cold water. If it gets stiff enough to draw into a thread take the pan off the fire. The mass if now poured out would give a very thick syrup or clear barleysugar; but if stirred briskly in the pan for a few minutes before pouring out it will begin to thicken and granulate, and if now poured out and cooled will furnish a hard white cake in which there still remains so much water thoroughly incorporated that, though it will not melt and run down as barleysugar does, it is very easily dissolved by the bees. The flour—common wheat four—is stirred in just before pouring out, a handful to each pound of sugar. The best form of cake is had by spreading a sheet of thin paper over a soup plate and pouring

about a pound into each. In ten minutes or more it may be lifted out and the paper taken off. The cake is then slipped under the quilt of a frame live, or laid over the feed hole of a skep, and warmly covered up. Mr. Rait, has lately discovered that the bees will to some extent store the flour as they do pollen, but generally it will be found that it is all used at once by the bees for their own nourishment or that of their young. Should anyone fall to get a good hard cake at first, it can be re-melted and boiled a little longer. The flour now in it will, however, cause it to boil over very readily.

QUEEN EXPELLED FROM HIVE (Sussex).—In all probability your stock lost its old queen late in the autumn. The bees raised another from the brood, but all the drones having by that time been destroyed, she remained unfertilised, and has been cast out by her subjects. If this is the solution of your case, the hive must perish before next spring.

MOVING A HIVE (O. B.).—You cannot at any time move your bees a distance of 50 feet at once without subjecting them to much loss and injury. Wait until the spring, when the bees are vigorously on the wing, and then shift the hive gradually a short distance at a time, allowing between each removal a clear day of good working weather to elapse. On the first occasion of taking the hive out of the bee-house, stand it exactly in front of its previous entrance, so that the bees may become accustomed to its appearance out of the shed; after which, shift to the right or left, and a little backwards or forwards as the case may require. By these precautions you will lose few if any bees, but by attempting to move the entire distance at once the loss of bee-life will be very great.

- Bitterly cold, but very fine morning; overcast in afternoon; clear fine evening. Lunar halo 11.30 P.M. till midnight.

 Keen frost, bitterly cold N.E. wind, only a glimpse of sunshine in

- forenoon.

 5th.—Light snow in early morning, bright, clear, and very cold; mow showers during the day; slighly warm in evening.

 6th.—Cold, bright, and fine throughout; sun quite warm in forenoon; bit-terly cold evening.

 7th.—Intensely sharp frost early with much rime; slight fog in forenoon, but sun shining through it; warner towards evening.

 8th.—Slight snow in early morning, fine day, partial thaw; fine sky at sunset; cloudy evening.

 9th.—Dark cloudy morning, fine day, sunshine at intervals; slight fog 4 P.M.; a few flakes of snow about 9 P.M.

 Very sharp frost, but not of very exceptional severity, the minimum being 16:1° against 6.7° in 1860 and 1867.—G. J. SYMONS.

COVENT GARDEN MARKET .- DECEMBER 10.

OUR market has been so quiet in consequence of the late frost that there is scarcely anything to remark upon, the principal feature being the absence of vegetables and the temporary rise in their value.

From observations taken near London during forty-three years, the average day temperature of the week is 44.3°; and its night temperature 32.7°.

CHRYSANTHEMUMS FOR EXHIBITION.

HAT the Chrysanthemum is a favourite flower at this season is admitted by all—indeed it may safely be described as the queen of autumn flowers. My acquaintance with Chrysanthemums is of long standing, and I well remember having had the part care of a lady's garden many years ago in which they were grown largely in the open border fully

exposed and without any protection whatever;

there they bloomed profusely, and the borders were gay with them, but the climate was more genial than this. It was at Teignmouth in sunny Devon, where the warm sea tempered the cold winds, and where the soil on the red sandstone cliffs is warm and rich, there almost without any special treatment they grew in huge brilliant clumps. From that day to this I have been an admirer and cultivator of Chrysanthemums; and I have always endeavoured to grow them well, for when imperfectly

grown they are very disappointing.

The culture of Chrysanthemums is simple, and success greatly depends on attention to the plants during the growing season, and maturation of the wood previous to the period of flowering. Our friends in South Devon, I am told, can still grow and flower them under the protection of a warm wall, but to obtain Chrysanthemums in their fullest beauty we have to grow them in pots and flower them under glass. If, however, we can command sufficient artificial heat to exclude frost we are repaid by a supply of gay flowers from the end of October until the middle of December, and a few Japanese flowers may even be had later than this. The popularity which this flower has attained within the last few years is surprising; this fact is illustrated by the rapid increase of exhibitions all over England during November.

Cuttings are taken off as early as possible; but though I prefer the earliest, say about the present time, I do not object to cuttings taken during January and February. These are inserted in small pots, generally three or four cuttings in a 60-size pot. The soil employed is light, and contains a large proportion of silver sand. The pots are then placed in a cold frame, protection from frost being afforded. If cuttings are taken late moderate heat will help to forward them, but cuttings struck in a cold frame are sturdier and hardier than those that have been nourished in warmth. As soon as the cuttings are well rooted, which if inserted early will be about the end of February, they are potted singly and returned to the cold frame. The frame is ventilated on all favourable occasions; in fact, on mild days the lights are drawn entirely off. About April the plants will be benefited by a second shift, this time into 32-size pots, using a compost with more loam than at the first potting, and a small stick is placed to each plant, which assists the stem to grow straight and erect. Return them to a cold frame until all fear of frost is past, when they may be placed out on any open space. Opinions differ slightly as to the exact time for their final potting. About the last week in June is as near a fixed period as I can name, for very often a gardener has to be guided by circum-NO. 977 .- VOL. XXXVII., NEW SERIES.

stances, and frequently about this time there is much other work requiring to be done. For this shift employ a compost of two parts of good yellow loam, one part of welldecomposed manure, and sufficient sharp sand to make the whole porous. The pots should be efficiently drained, placing a layer of the roughest portion of the compost over the crocks before filling-in the soil. Pot firmly. My collection this year was not finally potted until the 12th of July, which I consider fully a fortnight too late, and I well remember a friend on passing by them as they stood in their small pots pleasantly remarking, "There is no prize cup to be obtained by those plants this year, Moorman!" Within two days the whole collection was potted, and produced plants and flowers which exceeded my expectations as well as those of my friend, whose kind rebuff at the potting time I have so often thought of. At the time the plants received their final potting they were placed along the side of a garden path open to the full midday sun, in which position they the more readily matured their growths. It is better, especially for some time after potting, to err on the side of not giving sufficient water than to saturate the soil, especially

if it is slightly tenacious.

For untrained plants which are grown to supply flowers for cutting and exhibition, 8 or 9-inch pots are large enough. Careful watering and placing strong tall supports to the plants are all they require until about the 21st of August, when daily attention is requisite, for good flowers cannot be obtained without disbudding. In the majority of cases it is not wise to take the first bud that appears prior to this date, especially in strong plants. A second growth is made, and this should supply the flowers unless in very weak plants and some varieties. Until the middle of August the plants when grown in a natural manner without stopping have only one long straight shoot. At the extreme point of this growth a flower bud will appear. It is not this bud that it is advisable to retain, but the flower buds which will be found at the points of the three or fourbreaks that are soon made if the plants are in a good healthy condition. There are a few varieties which will throw fine flowers from the first buds, but in most cases they come coarse and rough. If the plants are allowed to break into growth a second time every shoot multiplies. into three or four more shoots, and the flowers are generally small and worthless, so it is necessary to disbud freely from the three shoots made about the 20th of August, reserving the central bud which generally produces the largest and best-formed flower. By this time the pots will have become full of healthy roots, and the plants will be benefited by the application of stimulants. But what to give them becomes the question. Amies', Clay's, and Standen's patent manures, guano, sulphate of ammonia, &c., are all good, but they must be given cautiously. I find no better liquid manure for Chrysanthemums than the diluted drainings of the farmvard and soot water, supplying it frequently and weak, and if at any time the surface of the soil appears coated over stir it with a stick. This will allow both water and air to penetrate it freely. About the first week in October the plants should be placed in a light airy glass structure; there they will advance rapidly into bloom, and will require NO. 1029 .- VOL. LXII., OLD SERIES.

copious supplies of water. I continue supplying weak liquid manure all through this period. Many of the varieties with long petals, or more correctly florets, such as the Empress of India and the Queen, fill-up better in the centre by being tied face downwards.

The difference between some large flowers when seen growing on the plants and when arranged on an exhibition table is very remarkable. In the hands of a good "dresser" a flower which is large but coarse while growing is so manipulated that when set up on an exhibition board it appears neat, full, and solid. I will not now express an opinion as to whether it is right or wrong to alter the appearance of these flowers by "dressing;" it is sufficient for my present purpose to state that unless coarse flowers undergo a certain amount of manipulation it is useless to enter them in competition against "dressed" flowers of an almost equal size. Why Chrysanthemum flowers are not exhibited with foliage as grown, in the same way as we exhibit Roses, I do not know, except that we in a measure bow to the dictate of fashion, which is to set them up pinioned in wooden cups, on painted boards, all neat and trim. Nearly all societies allow flowers to be "dressed." This "dressing" is simply drawing out all short, curled, and irregular florets from the centre of the flower, which in most flowers are shorter than the outside florets; the remaining florets are regulated and the blooms placed in hollow cups, which draw the outer or long florets over the hollow centre. A neat flower is then produced. Many flowers, such as those of the Mrs. G. Rundle type, cannot be improved by dressing; these and a few others come by high cultivation so near perfection that the gardener's art cannot assist them further. These remarks apply prinart cannot assist them further. The cipally to the large incurved varieties.

JAPANESE.—The rising popularity of this section of the Chrysanthemum is evinced by the numbers now in cultivation and the interest with which the general public linger around the collections staged at the various exhibitions. For years they have been looked upon by growers and florists as curiosities, but they are now becoming appreciated for their decorative value. They were first introduced by Mr. Fortune from Japan in 1860. I have grown almost every procurable variety, and there is very little doubt that had the late Mr. John Salter lived to experiment on this section a few years longer we should have witnessed some grand results. We seldom see fine specimen plants of this section; the best yet produced were some excellent standards exhibited by Mr. Brett at the Westminster Aquarium this autumn, which were very striking.

With respect to raising new varieties the credit is due to our continental friends, especially to M. Lemoine, for varieties supplied to nurserymen that have proved such acquisitions during the last three or four years. Some of the oldest varieties are still not surpassed in size and colour; there are others that are much too small for exhibition purposes, and are only worth growing to form a complete collection. For the future it will be a complete fallacy to say that they are so much later in coming into bloom than the other sections, for James Salter, Bouquet Fait, Elaine, La Frisure, Madame Lemoine, and Gloire de Toulouse are amongst the first to expand of all the sections. These are quickly followed by Fair Maid of Guernsey, Fulgore, Red Dragon, Fleur Parfait, Cry Kang, Hiver Fleur, M. Ardene, Nuit d'Hiver, J. Delaux, Bronze Dragon. Peter the Great, leaving Bismarck, Criterion, Plantagenet, Yellow Dragon, Madame Bertie Rendatler, Fulton, Mdlle. Moulise, The Mikado, Meg Merrilees, and Grandiflora, &c., to bring up the rear. This list by no means exhausts the good varieties worth growing, but every variety named I can highly recommend for size, quality, and distinctness, as well as being all free and good growers, with the exception of The Mikado, which is a lateblooming variety. To those who are about forming a collection of fifty varieties the following may be added in addition to those already named, very many of them being of equal merit to those above mentioned—viz., Arlequin (Lemoine), Garnet, Abd-el-Kadir, Sarnia, Comtesse de Beauregard, Mad. Godillot, Baronne de Prailly, Ne Plus Ultra, Apollo, Ethel, Jane Salter, La Nymphe, Tendresse, Erecta Superba, Magnum Bonum, The Cossack, Dr. Masters, M. Crousse, Leopard, Red Indian, The Daimio, Empero Nicholas, and Tokio.

Many other varieties I could name, but the above are all tried and well known, and without an exception can be grown to a size suitable for exhibition. In order to cut twenty-four distinct blooms on a given day it is requisite that many more varieties be grown than the number required, for it is impossible to cut twenty-four blooms distinct from only that number of varieties: some will have passed their best, while others

may not be sufficiently expanded. The diversity of forms in these Japanese flowers baffles the dresser's skill, except it be Elaine, which can be scarcely termed a real Japanese flower. Its size and chaste purity place it as one of the finest of flowers, and I should be sorry to see it displaced from this section; likewise Peter the Great, a very pleasing yellow, but almost bearing the characteristic of a badly incurved flower. Many other varieties have departed from the original grotesqueness so peculiar to the older varieties, and appear to display markings of a mixture of Chinese blood. But considering how closely placed the two countries are, and the sportive character of the Chrysanthemum, is it not probable that seedlings raised may vary in type without any particular attention being paid to hybridising? One very old and tried favourite of mine, Triomphe du Nord, has been for some years admitted in the same exhibitions as a Japanese and as a reflexed flower. I suggested to the Committee of the Kingston Chrysanthemum Society that it should be admitted amongst the Japanese and not amongst the reflexed, in which views the Committee concurred. This fact has given rise to some discussion on the classification of several varieties. It is a very good variety and does not disgrace a Japanese collection, while many newer varieties bear a great resemblance to the old Triomphe du Nord.

For a list of the best incurved varieties see page 31 of the Journal of Horticulture of January 9th of the present year, and refer also to the reports of exhibitions. Other sections of Chrysanthemums and varieties suitable for decorative purposes will be referred to on a future occasion.—J. W. MOORMAN.

AGAINST HARD PRUNING .- No. 3.

VERY elaborate directions are given in the standard works on gardening for training Peach trees in the fan shape, and beautiful pictures are presented to us showing how they ought to be done. First, beginning with a maiden plant, it has to be cut down and so manipulated that it will produce two shoots of equal strength, which are to be employed as a basis for forming the two wings necessary to this mode of training. The second year these two shoots have to be cut back and be succeeded by four shoots-i.e., two on each side. The third year brings us to another decapitation; and then after the sub-sequent growth is made, when the fourth year will be dawning upon us, we shall be supposed to have six or eight regularly disposed equal shoots, and we shall call it a dwarf-trained tree. Such a one we can procure from a nursery for 5s. or 7s. 6d., and I am sure I do not envy the nursery man either the trouble of or the reward for producing such a tree. It is true there is not much to see for our money, but if any one of your readers has an idea that the charge is excessive let him try his 'prentice hand at the art, and starting by working a dozen stocks next year, if he succeeds at the end of 1884 in producing three well-ripened evenly balanced trees he will be tolerably successful. It is true the nurseryman sometimes gains a year by inserting twin buds or even two buds on opposite sides of the stock, and sometimes by encouraging three shoots on each side of a two-year-old cut-back. But I suspect all the gains in this direction will not compensate for the various losses; and when we take into consideration the great value of his land, his enormous taxation, the handsome salary of really skilful and trusty propagators and managers, with the many bad seasons, we are forced to admit that his productions are a marvel of cheapness.

We will suppose that few will care to wait four years before they possess the framework of their future tree, but knowing the object of their desire is already in existence and can be had for a reasonable sum, will prefer to dip their hands in their pockets and start at a point which, although requiring considerable skill, is not so difficult as the work already accomplished. Starting, then, with a dwarf-trained tree, it is generally recommended to cut it back hard for a year or two in order to enlarge the framework to get it into form for filling from 15 to 20 lineal feet of wall. Now, supposing we always had good seasons and the trees met with no accident, we might in the course of ten or twelve years have one or two trees out of a score which would fill their allotted space and approach pretty nearly the symmetrical picture in our instruction books. Indeed, with all the drawbacks of our climate I have seen one or two beautiful trees in my time, but what about their companion trees? I expect most of your readers know too well. Even those trees which did approach to something like the ideal picture did not long retain their symmetry, and all who

have studied the subject even superficially must have come to the conclusion that we have to wait a long time for results

which when attained are far from satisfactory.

Well, then, as perfect fan-shaped trees are almost out of the range of possibility why all this cutting and waiting? If you will buy fan-trained trees do not cut them a bit more than is necessary for balancing them and removing unripe wood. The sooner they cover your wall with good moderate-sized growth the more fruit you will obtain; while the more you apply the knife the sooner will that decay commence which no amount of skill at present has been able altogether to prevent. But I do not consider either the Peach or the Apricot suitable for fan-training at all. They both abhor the knife; and if a tree when brought from the skilful treatment it receives in a nursery is ever so well balanced the knife has already done its work; and I very much question that if all the fan-trained young Peaches and Apricots in the kingdom were dissected and cut into pieces an inch long, there would be found one which had not a portion, however small, of its framework so much injured that it had commenced to decay. We know that the bark will grow over small portions of dead wood, and branches which contain such will even bear fruit for years if no severe check comes upon them; but under adverse influences they will succumb, and in pruning we often find traces of dead wood where it was not suspected.

Whether for indoors or out I prefer commencing with selected maiden trees, not overstrong, but well ripened, and which have never had a knife applied to them. The maiden stem is retained its full length, and as many of its laterals are laid in on both sides as there is room for without crowding. The trees are placed about 5 feet apart and upright. The laterals, which are to form the future main branches, are trained with their points a little the highest, and the usual disbudding and stopping is strictly attended to. There will be some blanks among the branches at the first training, but they will generally be sufficiently filled up by midsummer from a selection of the wood buds which start in great numbers from the main stem. The rest of the training will, I think, suggest itself to those who understand the mode of bearing of the Peach or Apricot. The stem and starting point of the main branches are similar to those of a horizontally trained Pear, but instead of being horizontal we aim to give the branches an angle of about 35°. Many trees so treated will bear a few fruits the second season after planting, and the third season they will cover a moderately high wall. This mode of training is the simplest I know of. It fills a wall very quickly, and the plants will be likely to last longer than cordons; for if we have a succession of fine seasons in store for us every other tree can be removed, and those remaining will extend without changing our mode of training. Fan-training can only be learned by actual experience. Most labourers and boys are very slow to understand it. It requires ten or twelve years to fill a wall, and that, I believe, is more than the average life of a Peach tree in our climate.

The three best successional Peaches are Hales' Early, Bellegarde, and Barrington. Among Nectarines the place of honour must, I suppose, be given to Lord Napier; but Pitmaston Orange is difficult to surpass for outdoor culture, and in dull seasons I am of opinion that the yellow-fleshed varieties retain their flavour better than the others. Violette Hâtive is one of the best for forcing.—WM. TAYLOR.

THE CULTIVATION OF THE AURICULA.-No. 1.

AT page 442 "D., Deal," mentions that Mr. Woodhead grows his Auriculas in glazed pots. He does not, however, state their size. For the information of those desirous of trying them, I may state that the pots he uses in no case exceed 5 inches in diameter at the top by about the same in depth. A large proportion of this space is occupied with crocks with fibre on the top, so that the amount of compost in which the plants are grown does not exceed 2 inches in thickness, and frequently not more than 1½ inch. In my experience of the Auricula, which extends over some thirty years, I have never seen plants do better than when grown in this manner. In no case do the plants appear to suffer from having so small an amount of compost to grow in, as after they have made their spring growth the plants are simply immense, more like Cabbages than Auriculas. These notes are not made from one year's observation but from a number, so that it is no new fact. The pots Mr. Woodhead uses are made at a pottery near his place; they are glazed on the outside, and to a depth

of three-quarters of an inch from the rim of the pot inside. This answers two purposes: the first is, the plants do not require watering so frequently as when grown in the common pots; the result is that the manurial salts are not so soon washed away by the surplus water. I believe it would be simply impossible to grow some varieties in common pots of the same size, as they would be continually suffering from want of water in hot dry weather. The only fault I can see in the pots is the glaze itself (the common brownware glaze), which in my opinion is too dark, and will be liable to absorb a great amount of heat if the sun happens to shine on the pots, more particularly the front row if the plants occupy a southern aspect. This, however, can be easily remedied by having a paler glaze, say a drab or buff, which can be obtained without increasing the cost.

With respect to Mr. Llewelyn's plan with offsets and seedlings, it is not new to me, as I used to plant all my offsets in beds the first year. It has, however, one great objection, and that is it is nearly impossible to clean the plants from aphides, as the leaves lie so close to the top of the soil; it is only by hand-picking that the plants can be kept clean. Where the collection of seedlings and offsets consists of six or seven thousand plants, as will be the case with Mr. Woodhead in the coming season, this would be simply impossible. The plan he adopts, and in my opinion it is far the best, is to grow his plants in shallow boxes 24 inches long and 8 inches wide by 3 inches deep, filling the boxes half full of crocks. A box of this size holds twenty-four plants. Boxes of this size are easy to move about, and can be placed anywhere conveniently. Mr. Woodhead has both frames and houses built to accommodate these boxes, and where the plan is uniform, as it is with him, it is an agreeable sight.

In conclusion I may say that Shobden Head is one of the latest places in Yorkshire, being 1000 feet above the sea level, the highest part in Yorkshire where florists' flowers are grown,

-GEO. RUDD.

PROTECTION FOR FRAMES AND PITS.

DURING the last few years I have tried various protecting materials for frames or pits, and observed the practice of others in this respect; and though the present period of frost has passed away, there is no guarantee that the winter has ended. It thus becomes of primary importance to consider the best and cheapest protecting material. Mats are a protection against only a few degrees of frost. I have tried old woollen rugs, and on account of their texture and non-conducting properties they are much better. Snow I have allowed to remain on the frames containing Pansies, Auriculas, Carnations, Campanulas, &c.. With about 18 inches of Oak leaves placed at the bottom of the frames that give but a degree or two of extra heat, and with dry hay—as fine as can be procured—placed over and around pits or frames, I have the following plants in good health at present, though my thermometer outside registered 14° of frost on two mornings during the past fortnight. Nothing is cleaner, more easily removed, and generally within the reach of all than hay. It must be remembered, however, it is not to be removed until the frost goes. Quite uninjured are Cinerarias, Primulas, Calceolarias, Petunias, Heliotropes, and Cape and other Pelargoniums, Fuchsias, Myrtles, Cytisuses, Coronillas, Daphne, Nerium Oleander, Passiflora cærulea, and Hoteia-Although I generally find Justicias set down as stove plants they are among the healthiest-looking of those already mentioned. Acacias, Epiphyllums, and a large assortment of Tuberous Begonias I removed to warmer quarters before the frost, but believe they would have been equally secure. In such pits I start all my bulbs, and very healthy and forward they now look. Cyclamens are now flowering freely.—W. J. M., Clonmel.

THE WEATHER IN SOUTH WALES.—During the last ten days the weather has been very severe for this part, from 12° to 18° of frost occurring nightly. The greater part of October and most of November were characterised by finer weather than we experienced all summer, and we expected one of the old mild winters, but at present there is every indication of the weather being as severe as last season. We have not had any snow, but white frosts and cutting east winds have already done much injury to such tender vegetables as Cabbages, Broccoli, Spinach, &c., which are about half the size they were a fortnight ago. All the fine heads of the Hydrangeas have perished, but of course as yet nothing can be said as to what

damage may be done amongst the more tender shrubs, only I fear they are not in such good condition for withstanding frost as they were at this time last year .- J. MUIR. Margam Park.

STORING GLADIOLI BULBS.

In answer to "WYLD SAVAGE" at page 440 of your last issue as to the practice of lifting the Gladioli in autumn I should like to add my experience. When appointed to the management of these gardens my predecessor, a thorough practical man, left the bulbs in the ground with a covering of sahes over each cluster, naturally thinking they would be safe, but when the borders were dug over scarcely a trace of the bulbs was to be seen; they had all decayed in the ground. In consequence I had to obtain a fresh supply, which were blooming profusely till the first sharp frost cut them off. I had them lifted and laid in a cool house in leaf mould, and have now picked them over and stored them away in a box of sand till spring. So far as my experience goes I do not think it a safe plan to leave them in the ground during winter, and shall never adopt it. Ours is a wet stiff soil, about 18 inches deep, on a bed of clay .- THOS. PITTS, Castlecroft, Wolcerhampton.

THE NATIONAL ROSE SOCIETY.

The annual general meeting of the above Society was held at the Horticultural Club, Arundel Street, Strand, on Thursday, December 11th. In the unavoidable absence of Dr. Hogg the Rev. J. M. Fuller was voted to the chair. Amongst the members present we noticed Messrs. H. Appleby, Dorking; J. Brown, Manchester; B. R. Cant, Colchester; Capt. Christy, Westerham; J. Cranston, Hereford; J. Cutbush, Highgate; C. Davis, Banbury; Rev. F. H. Gall, Hitchin; J. Laing, Forest Hill; J. Mayo, Oxford; J. W. Moorman, Kingston-on-Thames; G. W. Piper, Uckfield; G. Paul, Cheshunt; G. Prince, Oxford; W. Rumsey; T. F. Rivers, Sawbridgeworth; W. G. Sharpe, Horsham; J. T. Strange, Aldermaston; and the two Hon. Secretaries, Rev. H. H. D'Ombrain and Mr. E. Mawley. A letter expressing high appreciation of the objects of the Society was read from Mr. James McIntosh of Duneevan, who regretted that his delicate health prevented him attending the meeting. The minutes of the last Committee meeting were next read, which related the fixtures and places nominated for holding the Society's exhibitions for 1880, subject to the approval of the meeting. THE annual general meeting of the above Society was held at subject to the approval of the meeting.

The Rev. H. H. D'Ombrain said, with respect to the fixture of

July 3rd, for holding their Show at the Crystal Palace, he had seen the Deputy Manager, and made arrangements so that the members of the Rose Society should be admitted to a private view half an hour before the general public were admitted, on condition that he undertook that the tickets were for members

only, and not transferable.

Several members asked if the ladies that subscribed would be allowed the same privilege. It was unanimously agreed that they would, and thought it might be an inducement for many more to

join the Society

Two places had been suggested by the executive for holding the provincial exhibition for the ensuing year, Liverpool and Cheltenham being the places named. Mr. D'Ombrain said that he had put himself in correspondence with the above-named places, and that Liverpool had replied with many thanks, but were unable to entertain them. He believed that the rules of the Society not sanctioning two-day Rose exhibitions proved the greatest bar to Liverpool not accepting them. From Cheltenham he had received a point-blank denial, and failing both of these places he wrote to Manchester on the same terms as before, and mentioned the 17th July as the date of the Exhibition. Mr. Findlay accepted, but thought it too late, and named the 10th.

Mr. Chanston.—Then am I to understand that the idea of a

moveable Society is abandoned for this year?

THE SECRETARY.—We have arranged for Manchester subject to your approval. The feeling of the last meeting was that it should be moved.

Mr. G. PAUL.—I think we are all agreed that it is desirable to remove it to some other place if possible. I think we ought to be a year in advance with a place and ought now to be making

suggestions and preparations for 1881.

The Rev. H. H. D'OMBRAIN thought that it would be very desirable if the members would use their influence privately in securing a suitable place for another year.

The question of Manchester for 1880 was then put to the meet-

ing and carried unanimously. A discussion next arose respecting the date for holding the Exhibition at Manchester. Mr. Brown, speaking as a Manchester man, said that the 19th of July this year was found to be too early for Roses in that neighbourhood, he, therefore thought that the 10th of July would be too soon in ordinary years, he would have much pleasure in proposing the 17th. Mr. Paul seconded the motion, which was carried unan mously.

The following report and financial statement was read and adopted, which shows a balance in hand of £56 19s. 1d.:-

The season of 1879 will be long remembered by Rose-growers, as well at all interested in gardening, on account of the disappointments caused by a abnormal character; it is therefore a matter of great satisfaction to be committee that they are nevertheless enabled to congratulate the Explosion

committee that they are nevertheless enabled to congratuate the memors on the presperous condition of the Society.

FINANCIAL STATEMENT.—In the last Report it was intimated that although there was an apparent balance in hand of £25, yet, that measured wards of £60 continued still owing to five of the principal exhibitors of £37, there really existed a somewhat large deficit. The Committee have was however, the pleasure of stating that not only has this debt, on account of the St. James's Hall Exhibition, been entirely cleared off, but that at the present time there remains a clear balance in the Treasurer's hands of £36 19s. 1d.

PRINCE METALE.—Our price metals have been much appreciated by the

present time there remains a clear balance in the Treasurer's bands of 256 19. 1d.

PRIZE MEDALS.—Our prize medals have been much appreciated by the various societies which have availed themselves of the privilege of obtaining them. A list of these Societies, together with the names of the winners of the National Rose Society's medals, will be found appended to the Report.

SPECIAL PRIZES.—As unusual number of special prizes has this year here offered for competition at the Crystal Palace, and the Committee desire especially to thank those Members who have thus shown their generous sympathy with the objects of the Society.

MEMBERS' PRIVILEGES.—By the arrangements made for 1869 Members subscribing £1 will be entitled to one Member's ticket (not transferable) and two transferable tickets. All these tickets, are available for either of the Society's Exhibitions; but the Member's ticket, which is a new feature, confers the special privilege of admitting to a prate view of the Crystal Palace Exhibition half an hour before it is operated ouring the day.

More gratifying perhaps than even its financial success and the extent its operations has been the recognition of the Society as the authority on all matters connected with the Rose, its culture and exhibition. The rules for judging have been largely used, while the concise series of hints on Rose growing recently issued have also been much appreciated. Several Esse nurserymen, we notice, have introduced the latter into their catalogues for the present year. The Committee again look forward hopefully, feeling assured that their efforts on behalf of the queen of flowers will be heartly encouraged by the Members; and, in conclusion, desire to thank the best Secretaries for the able and zealous assistance they have given in making the Society more known and valued. the Society more known and valued.

A. OHRISTY, GEORGE P. HAWTREY, } WILLIAM SCOTT, Hon. Treasurer.

George Baker, Esq., Reigate, was added as Vice-President, the following being the revised list of officers and committee for 1880:—President: the Rev. Canon Hole; Vice-Presidents, the Hon. and Rev. J. T. Boscawen, James McIntosh, Esq., George Baker, Esq. Committee: H. J. Adams, J. Appleby, J. H. Arkwiight, R. N. G. Baker, H. Bensted, Rev. H. B. Biron, T. F. Burnaby-Atkins, Rev. J. B. M. Camm, B. R. Cant, R. B. Cater, Rev. A. Cheales, Capt. Christy, R. Cordell, J. Cranston, J. L. Curtis, H. Curtis, J. Cutbush, C. Davies, J. W. Finlinson, J. Forsyth, Rev. J. M. Fuller, Rev. F. H. Gall, T. Graveley, G. P. Hawter, Dr. R. Hogg, J. Hollingsworth, T. Jowitt, L. A. Killick, J. P. Kitchen, Rev. H. W. Kynnersley, J. Laing, J. Lakin, Dr. M. T. Masters, J. Mayo, H. K. Mayor, J. Mitchell, W. Mount, W. Newall, G. Paul, W. Paul, J. D. Pawle, Rev. E. N. Pochin, G. Prince, T. F. Rivers, S. M. Robins, W. Robinson, A. G. Soames, J. T. Strange, J. Tinsley, C. Turner, H. J. Veitch. Hon. Secretaries: The Rev. H. Honywood D'Ombrain and Edward Mawley. Hon. Treasurer : William Scott.

is anything conducive to the interest of this Society that this meeting should discuss?

Rev. H. H. D'OMBRAIN.—I think we ought to point out authoritatively whether Hybrid Teas ought to be exhibited among the Teas and Noisettes. My own opinion is that they should not.

The general opinion of the meeting was they should not be admitted, but at present there appeared considerable difficulty in

settling the matter, so the subject was allowed to drop.

Mr. CRANSTON said that the best judges on the Rose should be delegated to adjudicate the class for the fifty-guinea cup, given by himself, which is to be finally won this next year. He should like if possible for that meeting to nominate two nurserymen Rose-growers and two amateurs, with the option of their calling in a fifth if needed. After some little discussion on this matter, which the meeting felt was important, it was ultimately agreed that the number of judges should be appointed, and as soon as they had awarded the cup prizes they were to return to the other classes allotted to them.

The schedules of prizes for both the Crystal Palace and the Royal Botanic, Manchester, were revised. The most important alterations were that in class 1, seventy-two, distinct, nurserymen.

Mr. John Hollingworth offered a ten-guinea cup; this is to be supplemented with a £5 prize also. Mr. Thomas Hollingworth offers a six-guinea cup which we understood was to be given for eighteen Teas. Mr. B. N. G. Baker gives a ten-guinea cup to amateurs, and Mr. G. Paul a cup of the same value to amateur growers for a collection of twelve varieties of Cheshunt-raised Roses. The "Journal des Roses" offers a silver gilt medal, which this meeting decided should be awarded for twenty-four flowers in eight trebles, one flower of each to be in its full beauty, the other as an opening bud, and the third a mere bud.

The most important addition to the schedule of prizes for Manchester was the making of an extra class for nurserymen residing within thirty miles of Manchester, which is intended to include Liverpool.

Cordial votes of thanks were accorded to the two Secretaries, Rev. H. H D'Ombrain and Edward Mawley, Esq.; to W. Scott, Esq., the Treasurer; to Captain Christy, and G. P. Hawtrey, Esqrs, who had acted so ably as Auditors; and finally to the Chairman, the Rev. J. M. Fuller, for the able manner in which he had conducted the business of the evening.

PRESENTATION TO MR. D'OMBRAIN.

The CHAIRMAN then said, as there were some then present who possibly wanted to leave town, he had very great pleasure in presenting to their Hon. Secretary, the Rev. H. H. D'Ombrain, a testimonial as a slight recognition of the services Mr. D'Ombrain had rendered to that Society and to floriculture in general, and hoped that he might be spared to write a great many prize lists yet. The testimonial consisted of a most beautiful and charte yet. The testimonial consisted of a most beautiful and charte silver inkstand bearing the following inscription:—"Presented to the Rev. H. Honywood D'Ombrain, December 11th, 1879, with the affectionate regard of many friends, and in grateful recognition of the services rendered to floriculture by his writings and practical support, more especially to the Rose, by establishing the National Rose Society." There were two silver candlesticks the National Rose Society." There were two silver candlesticks to match and a purse of gold, the whole placed in an elaborate inlaid case. The list of subscribers to the testimonial contained amongst others the names of most of the leading rosarians, ama-

teur and prefessional, in the kingdom.

Mr. D'OMBRAIN, after thanking all very kindly, said if there was any word he took objection to it was the word "establishing."

He suggested the Rose Society, but did not establish it. The members subsequently dined together, and a most harmonious evening was spent, Captain Christy taking the chair. Notwith-standing the severity of the weather and the distance many of the members have to travel the meeting was well attended, as many as ten different counties being represented; this speaks well of the love for the Rose, even in the midst of intense frost and snow .-- M.

SCHIZOSTYLIS COCCINEA.

In the conservatories at Oakholme, Sheffield, there is now a very fine display of this valuable winter-flowering plant. Mr. Hannah, the able gardener, has for a number of years past grown this plant remarkably well, and he expresses surprise that it is not more generally grown and appreciated by gar-deners for the embellishment of the conservatory in November and December.

These plants, which are grown in 10-inch pots, have from twenty-five to thirty spikes of flowers, thrown well up above a mass of bright green and healthy foliage, and much resembling spikes of miniature Gladioli. Grouped amongst Chrysanthemums they are most effective. The mode of culture is to repot them in a good compost soon after they have done blooming, and to keep them in the pots all the summer, standing them out in a sunny place, and supplying them liberally with liquid

Mr. G. PAUL.—I don't know whether it strikes any of you if there | manure. He tried planting them out and lifting them again in the autumn a few years since, but found that plan would not answer in this northern district; he obtained healthy growths but few flowers.-W. K. W.

GOSSIP ABOUT CALOCHORTI.

HARDY herbaceous plants are at the present time very numerous, and when we hear the term "herbaceous" used we are reminded at once of its great elasticity. It includes weedy as well as good and showy species; and when you speak to some horticulturists about such plants your enthusiasm often receives a rebuff, and they say "weeds," forgetting most likely that many most attractive plants are included in that class. Now, we do not advocate the general cultivation of all known hardy plants, but if a careful and good selection is made we are bound to say that they will give as much pleasure and satisfaction as any plants, and amongst the most beautiful are the subjects of this paper.

In the Calochorti we include the species of the genera Calochortus and Cyclobothra, regarding, as is now the system, the latter as at the most only a sub-genus of the former, since the structural variation is so limited that it does not deserve generic rank. The chief differentiations in the genus Cyclobothra from Calochortus are in the outer or sepaline divisions of the perianth being bearded, by all the perianth divisions being furnished with a honey pit in the centre, which forms a gibbosity on the outside, and by the stems producing viviparous buds in the leaf axils. All the known species are found in Mexico, California, and parts of North-West America, growing usually in very arid situations, occurring both in valleys and on the sides of small hills and mountains, but always in dry places where the soil is exceedingly light and sandy, a fact which furnishes the cultivator with a good hint as to the best kind of soil to plant or grow them in. We know of no flowers more exquisitely and peculiarly coloured. It is difficult in some instances to describe the coloration of the flower. Take, for instance, the lovely C. venustus. They expand their flowers from May to September if a good selection of species is made. They are not of coarse and large growth, but in any portion of their existence above the ground they are handsome. Linnæus considered their beauty in every respect when he designated them by the name of Calochortus, which means "Handsome Grass.

As to their cultivation it is easily described. They require such treatment as most bulbous plants require. The soil which suits them best is an equal mixture of good fibrous loam, peat, and sharp sand, planting them about 4 or 6 inches deep in a dry sunny position, and allow them to remain without being disturbed every season. It is much to their advantage to give them a good depth of soil with a perfect drainage, and then you may safely let them remain year after year, and without any protection they will always produce good flowers. Below we have given a list of the best kinds in cultivation, and if they are secured, and the bulbs good, the result will be satisfactory to the cultivator.

Calochortus albus (Cyclobothra alba).-A lovely species, growing about 1 foot high, with copiously branched stems bearing numerous pure white finely fimbriated flowers, which last a long time in perfection.

C. citrinus.—A recently introduced and grand species, taller than the last. The flowers are very large. The one we refer The flowers are very large. The one we refer to measured about 4 inches across, erect, of a bright golden yellow ground colour, thickly dotted with small deep crimson spots, also covered with golden woolly hairs, and the edges of the perianth divisions beautifully fringed. This is truly one of the finest in the genus, and it is interesting to notice the large amount of variation, some of the flowers being margined in varying proportions with purple and crimson.

C. elegans.—This is a charming little species, growing from 6 to 9 inches high, with much-branched stems bearing several flowers, sometimes as many as eight or ten. The flowers are much smaller than those of the last, of a bluish purple colour. deepening towards the centre into a deep velvety purple, and the whole of the internal surface is covered in hairs, whichgives it a peculiar appearance. This species sometimes flowers as early as May, and lasts a long time in bloom.

C. lilacinus.—This species also grows about 6 inches high, with the flowers umbellately arranged. The flowers are rather larger than the last, say about 1 inch across, of a dullish blue colour, and sparingly bearded.

C. luteus.—A very handsome kind of stronger and taller

growth, freely producing its bright yellow flowers, which vary considerably; some with blotches of a purple colour, others without, while some are sparingly hairy. It is a very hardy

and beautiful species.

C. pulchellus (Cyclobothra pulchella).—A lovely species, growing about 1 foot high, with copiously branched stems, bearing several pendulous flowers of a bright golden yellow colour, freely bearded. This is one of the most floriferous of the set, and very charming. It commences to flower in May, and lasts till July very frequently. Plant it freely.

C. macrocarpus.—A very fine species, but as yet very scarce. It grows sometimes as high as 2 feet. The flowers are of a rich rosy purple colour, lighter towards the base, and copiously

bearded with yellow hairs.

C. splendens.—This is one of the oldest known in cultivation, and undoubtedly one of the best. It grows from 18 to 24 inches high, bearing several flowers, which when expanded are quite 3 inches across, of a rich rosy purple colour, with crimson blotches at the base of each perianth division, and

slightly hairy above the blotches.

C. venustus.—We think this was introduced about four years after the last (1836), and it is the showiest in the genus. It grows about 18 inches high, producing several flowers (from six to ten), which, as far as colour is concerned, are difficult to describe; they are 3 or 4 inches in diameter, with the upper part of the petals white, yellowish towards the base, terminated with a wedge-shaped heavy crimson blotch, also thickly dotted with crimson, and bearded; altogether the flower assumes a most peculiar and handsome appearance. There are several other species and varieties known, and are cultivated in limited quantities, such as Gunnisonii, flava, flexuosus, Leichtlini, &c., but those above described are the best.—T.

BOTHWELL CASTLE.

SEVEBAL months since I paid an agreeable visit to this place, which is situated on the north banks of the Clyde in Lanarkshire, about eight miles from Glasgow, three from Hamilton, and not far from Bothwell Bridge, which was the scene of an engagement on the 22nd of June, 1679, between the Covenanters and the King's army, commanded by the Duke of Monmouth, assisted by Claverhouse and Dalzell. For many generations the place has belonged to the Douglas family, and lately has by legal descent and heirship come into the possession of Lord Dunglass. The present gardener, Mr. Andrew Turnbull, has been head gardener here for fifty-one years, and during this long term of service Bothwell Castle Gardens have borne a good character, and been considered one of the many well-managed places in Scotland. The character of the place has drawn many noblemen and gentlemen to Mr. Turnbull for trained men to manage their gardens, and many of the men recommended by Mr. Turnbull have been good servants and great ornaments to their occupation or profession. Both the Thomsons (William and David) were "alips" from Bothwell.

The old Castle of Bothwell is a very ancient and striking structure, probably the most magnificent pile of ruins that can be found or seen in Great Britain at the present time. Some of the walls are 15 feet thick, and some 60 feet high, and some are well mantled with Ivy, Clematis, Aristolochia, and wild plants clambering up and growing out of the walls. This grand old pile of ruins stands high and on a charming spot overlooking the Clyde, which runs past it in a deep valley of great beauty, the banks of which are finely wooded. Right opposite the old castle, on the Blantyre side of the river, may be seen the remains of an old priory built on the edge of a perpendicular rock, natural masonry rising right out of the river, and more than half hidden by the foliage and branches of trees. This old castle, giving grace to everything around it, looks on a scene of picturesque beauty and grandeur. What is worth mentioning here is the fact that Bothwell gardens and grounds are open twice a week (Tuesdays and Fridays) to the public. Those that go in by the principal entrance have to write their names in a book, and this is all that is required for admission. The whole place-including farm, gardens, orchards, pleasure grounds, and woods-contains about 700 acres, and is enclosed by a good wall about 8 or 9 feet high, save on the south side, which is bounded and well protected by the Clyde river. Considering that the gardens at Bothwell are extensive and looked on as "a show place," it is remarkable that in them there is a comparative deficiency of glass structures. Both the

kitchen and flower gardens are protected by walls 15 feet high. and the walls in the vegetable department are covered with fruit trees well trained and nailed, every branch, from its base to its point, running out about as straight as a gun barrel. In the kitchen garden there are two Pine houses and a Peach house, and underneath the Peach trees, which were carrying a good crop of fruit, stood a fine lot of well-grown Azaleas. In the flower garden there are two houses well filled with Camellias. This flower garden, containing probably from 1½ to 2 acres of land, is edged out in Box, and requires many plants to cover the large borders and beds. Dwarf Dahlias were largely used for filling the centres of the large beds. They were planted thickly, more than one hundred in the centre of a bed, with ribbons around them of Geraniums, Calceolarias, Perilla, Feverfew, Tropæolums, Lobelia, and Violas. Generally speaking a ribbon of two or three colours only comes between the Dahlias and Box edging. The broad border, running the whole length of the garden, was well filled with large old Geraniums of various colours, and the 15 feet wall behind the border was covered, or being covered, with climbing plants to the top, chiefly with strong-growing scarlet Tropeolums. In this way Mr. Turnbull contrives to make his flower garden in its season an unbroken mass of dazzling flowers. Being without much glass he has to resort to shifts of various kinds to get plants enough to cover the ground. Dahlias, which are largely used, can be wintered, like Potates, in shels and cellars. His yellow Calceolarias are raised annually from seed, and thus from a pan or two of seed he can and does raise thousands of plants.

Outside and behind the walled gardens I saw two house filled with Zonal Geraniums, but I did not go into them. I was more anxious to see the Heath house at Bothwell, which stands alone about half a mile from the gardens. For more than forty years the Heaths of Bothwell gardens have been objects of interest and admiration to gardeners and others visiting the place. Since I was last there the old Heath house has been removed and an elegant new one erected in its place. The Rose garden near to the Heath house has been remodelled and greatly improved in appearance. The plants in the Heath house—numbering probably about two hundred, and some of them 3 feet in diameter—we found in the heyday of their summer blossom and beauty. Many on the plants are seedlings Mr. Turnbull obtained by crossing well-known named varieties, and seemed to us to be improvements on the parent plants. All the plants were healthful, and the flowers covering them were charmingly large, clean, and wax-like. The Heath house

is the gem of the gardens.

Another object of interest to me in these gardens was the old border of herbaceous hardy flowering plants, containing above seven hundred different kinds, all named and numbered for the benefit of the young gardeners who serve at Bothwell, and for their comfort and advantage there is a bothy for six men. On taking leave of Bothwell gardens, and on taking a retro-

On taking leave of Bothwell gardens, and on taking a retrospect of all we saw in them, we could hardly tell whether the venerable old castle or the venerable old gardener had made the deepest impression on our minds. There we found Mr. Turnbull—after fifty-one years of active faithful service, aged 76—full of gardening instincts and youthful-like enthusiasm; and though by a great misfortune—viz., his connection with the City of Glasgow Bank—he has lost every farthing of his savings for half a century, everything but his clothes having been taken from him and sold, we were charmed with his pleasant smiles and conversation, his buoyant and hopeful spirit. In this one situation he has served several honourable and noble employers with credit and satisfaction, and it may be said that Mr. Turnbull himself, if not in blood, yet in heart and life, is a true nobleman.—A. PETTIGREW.

SEVERE FROST AT CHIRNSIDE, N.B.

THE unprecedented lowness of the temperature on the morning of December the 4th is worth recording. As to the accuracy of that registered at Blackadder I was myself incredulous at the time. I have, however, seen the land steward since, who assures me that the register thermometer has been tested besides others and found to be accurate. The situation of the garden near the river Blackadder and the nature of the soil render it peculiarly liable to suffer from severe frost. Indeed, Dahlias and other tender plants are usually killed there a month earlier than at other places. I have no doubt that the temperature recorded, 23° below zero, was accurate; on the opposite side of the river on higher ground at Allanbank

the thermometer indicated 13° below zero; at Ninewells, not more than a mile distant, 8° below zero; at Chirnside Bridge 6° below zero. We have had no frost compared to this since 1860, when 5° below zero was recorded at Chirnside Bridge. There were three deaths in this immediate neighbourhood from exposure to the inclemency of the weather in one week, and numerous cases of severe frostbite have occurred. I sent the temperatures at the time to the Scotsman newspaper, and as I perceive that you have noticed them in the Journal with a note of interrogation following the lowest I consider it right to give you further information on the subject.—C. STUART, M.D.

DODECATHEONS.

I NOTICE in the Journal, on page 442, an article on Dodecatheons by "T.," who under D. Meadia mentions some varieties. A few years back in Prestwich near Manchester a Mr. Barlow resided, who raised a variety apparently between D. Meadia and its variety elegans, which seemed to be quite intermediate between both plants, and was sold out and grown in many gardens. Later on the same gentleman raised a splendid vigorous-growing white variety quite equal to elegans, but whether these two varieties are in existence now I am unable to say. I mention these, as I think your correspondent "T." has not seen them. I may also observe that the gentleman referred to raised Delphinium Barlowi, that good old herbaceous plant which has stood its ground for at least forty years, and is still one of the best border plants in cultivation.—

James Percuyal.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 16TH.

THE last meeting of the Society in the year 1879 was uncommonly bright and interesting for such an unfavourable season. Although the exhibits were not very numerous, they compensated for that defect in their general excellence. Messrs. Cannell, Miles, Dean, and Ollerhead's contributions formed the bulk of the floral display, Grapes being extremely well represented by collections from Messrs. Atkins, Wallis, and Roberts.

FRUIT COMMITTEE.—Henry Webb, Esq., in the chair. On this eccasion some excellent Grapes were exhibited; the immense bunches of Gros Guillaume from Mr. J. Roberts attracted especial attention. The Muscats from Mr. Goodacre were noticeable for their good form and high finish. Mr. J. Wallis, gardener to the Rev. W. Sneyd, Keele Hall, Stafford, sent a fine collection of Grapes, comprising eighteen bunches of six varieties. Lady Downe's were well ripened; Black Alicante, very good; Golden Queen, of medium quality; Gros Guillaume, handsome bunches, good colour and bloom; Gros Colman and Black Morocco were also well represented. A cultural commendation was awarded, and the Committee recommended the award of a silver medal. Mr. J. Roberts, gardener to the Countess of Charleville, Charleville Forest, Tullamore, exhibited two enormous bunches of Gros Guillaume Grape, which had been borne on one rod, and weighed collectively 42 lbs. A card affixed to the stand stated the same variety had in four years produced seven bunches, which in the aggregate weighed over 126 lbs. The Committee awarded a cultural commendation, and recommended a bronze medal. Mr. J. H. Goodacre, The Gardens, Elvaston Castle, Derby, sent two well-grown Smooth Cayenne Pine Apples; Mr. J. Coombes, gardener to J. Rolls, Esq., The Hendre, Monmouth, also sent two similar Pine Apples, and each exhibitor was awarded a cultural commendation. Mr. J. Atkins, gardener to Col. Lloyd Lindsay, Lockinge Park, Wantage, sent twelve remarkably handsome bunches of Muscat of Alexandria, excellently finished, and fine in berry. The same exhibitor also staged nine dishes of Apples and two of Pears in good condition. For the Grapes a cultural commendation was accorded, and a silver medal recommended; and for the Apples a letter of thanks was sent. Messrs. Carter and Co. of High Holborn staged two large heaps of Potatoes, Magnum Bonum and Scotch Champion; the latter variety was accoked, and the Committee expressed their opinion that it is remarkable for resisting disease, and

FLORAL COMMITTEE.—Dr. Denny in the chair. Few plants were exhibited for certificates, the collections principally being composed of Pelargoniums, Poinsettias, Cyclamens, and cut blooms of Chrysanthemums. Mr. H. Cannell, Swanley, Kent, was accorded a vote of thanks for a large collection of Zonal Pelargonium blooms in excellent condition and extremely bright and well formed. He also sent six well-flowered plants of White Veeuvius and cut flowers of Dahlia imperialis. Mr. C. Green, gardener to Sir G. Macleay, Pendell Court, Bletchingley, exhibited a plant of the

distinct and pretty tufted Saxifraga valdensis, and cut flowers of Dablia Maximiliana, a species similar in habit to D. imperialis, with pale purple florets. A vote of thanks was accorded. Mr. G. Wiggins, gardener to H. Little, Esq., Hillingdon Place, Uxbridge, received a similar recognition for a collection of incurved, reflexed, and Pompone Chrysanthemum flowers, which were distinguished by their neat forms and good colours for such a late period. Mr. J. Moorman, gardener to the Misses Christy, Coombe Bank, Kingston, was also accorded a vote of thanks for a collection of twenty-four cut blooms of Chrysanthemums, several of which were in good form. The best were Fulton, Madame Godillot, The Mikado, Princess Teck, and Hero of Stoke Newington. Mr. J. Osborn, gardener to H. J. Buchan, Esq., Southampton, was awarded a first-class certificate for a pretty Orchid, Oncidium Edwardi, which was bearing a panicle of small flowers with recurved sepals and petals of a purple tinge. Mr. W. Miles, West Brighton Nursery, Cliftonville, very worthly obtained a cultural commendation for a collection of plants of the Zonal Pelargonium West Brighton Gem, very dwarf, compact, and profusely flowered. Mr. H. B. Smith, Ealing Dean Nursery, Ealing, staged a very large collection of Cyclamens comprising about 170 plants, all in 48-size pots, vigorous, dwarf, even, and remarkably well flowered. The collection included many good varieties, and a first-class certificate was awarded for Baroness Burdett Coutts, of which the flowers were pure white, large, of great substance; the peduncles stout, and foliage prettily marbled. Mr. Ollerhead, gardener to Sir H. Peek, Bart., M.P., Wimbledon House, was accorded a vote of thanks for a large group of Poinsettias, including a variety named rosea that was exhibited with plants of P. pulcherrima to show its distinct character. The bracts appear smoother in outline and of a rosy scarlet tinge, which at a distance has, however, a somewhat dull appearance. Messrs. T. Jackson and Son, Kingston-on-Thamme

NOTES AND GLEANINGS.

RESPECTING SCALE ON FRUIT TREES, "A KITCHEN GAR-DENER" writes, "As this is the time of year when an attempt is generally made to clean fruit trees of scale and other insects, let me ask those who have trees infested with these destructive pests to try the remedy of syringing the trees thoroughly with water heated to 140?. Mr. D. Thomson recommends this in his fruit book, and it is a remedy as effectual as it is simple. Some kind of engine is the most convenient to apply it with, as the water is too hot to do it with a hand syringe."

—— AT a general meeting of the ROYAL HORTICULTURAL SOCIETY held on Tuesday last, Colonel R. Trevor Clarke in the chair, the following candidates were elected Fellows of of the Society—viz., J. Hume Burnley, Mrs. Grigg, K. J. Jerram, Mrs. Linklater, Vernon Lushington, Major James D. Mackenzie (of Findon), Charles Wm. Moriss, Henley Oliver Smith.

—— ONE who has to prune and nail in the cold weather advises all who have to stand on the cold ground during the winter to wear CORK SOLES in their boots, as they not only effectually keep the damp from the feet, but they are warm and a great comfort to the wearer.

— WE learn that, from trees on a south wall in Grinkle Park Gardens FRUIT equal in quality to what it usually is there in September was gathered on November 11th, of Barrington, Malta, and Noblesse Peaches. From an east wall Coe's Golden Drop was gathered in good order on the 28th of November, and at the same date Pond's Seedling Plums were also excellent.

—— THAT excellent late preserving and culinary hardy PLUM WYEDALE, which closely resembles Winesour, and is much grown in North Yorkshire, has not in the hill districts ripened perfectly, but in a semi-ripened state it makes good preserve, and in that state it has been much used this season.

—— "I HAVE," writes "R. P. B.," "CHRYSANTHEMUM LA NYMPHE this year for the first time, and think very highly of it as a producer of flowers for cutting. Its colour is soft and pleasing, and the flowers are very freely produced and not overlarge. Mrs. Dixon is another valuable variety for the same purpose. In addition to the above, Mrs. G. Rundle, Mr. G. Glenny, Elaine, Fair Maid of Guernsey, Julie Lagravère, and Venus, all produce large quantities of fine flowers for furnishing vases, &c."

- —— "A YOUNG PACKER" desires information through the medium of the Journal as to "the best mode of packing Grapes, whether in boxes or baskets, and about how many in each?" We will readily publish notes from those who can state their experience on the subject.
- MR. LAXTON writes as follows on the WEATHER AT BEDFORD:—"On the morning of the 2nd inst., at 8 A.M. the thermometer here at 4 feet from the ground registered 26° of frost; on the following night the lowest was 24° of frost, and during the night of Saturday last, the 6th inst., zero was registered. About 4 inches of snow fell on the 5th. Autumn Cauliflowers and Broccoli appear quite destroyed, and Tea Roses where unprotected are injured, but at the Experimental Garden the protection afforded by Pea haulm has saved a good many. The ground is, however, frozen hard."
- THAT fine ally of the Dracænas, CORDYLINE INDIVISAis an old greenhouse favourite of very easy culture, so that
 everybody having such a house should grow one or two plants
 of it. That this is not done is probably owing to the fact of
 its only being seen at flower shows under the guise of large
 specimens requiring more space than could be spared in the
 conservatories of small gardens. It is readily obtained from
 seed, the seedlings becoming large enough for decorative purposes in a year. We have not a more elegant plant for the
 dinner table, and with due attention to watering and sponging,
 small plants continue in good condition for a long time.
- At the end of November many trees of the COMMON OAK in Sussex had, writes a correspondent, hardly shed a leaf and much of the foliage was still green. Frost, snow, and wind have at length laid bare the branches. The fact of this tardy defoliation is worthy of record, forming as it does another of a series of the extraordinary peculiarities of a gloomy dripping summer and autumn.
- CAREFUL attention is requisite to preserve FINE-FOLIAGE PLANTS in good condition at this season. Frequent sponging is of great importance, and as this requires much time advantage should be taken of any cessation of work in the open air during rain or snow to do as much of it as possible. Woodlice, slugs, and snails are also sad pests among foliage plants, and as they are invariably busiest at night it is an excellent custom to walk through the houses as late as possible to catch and destroy every one of the marauders that can be found.
- WE are informed that during the summer of 1880 a STUDENT'S GARDEN will be opened in the Royal Gardens, Kew, where, under special regulations, students will enjoy the privilege of obtaining specimens for botanical investigation.
- MR. COWAN informs us that much damage has been done by the FROST IN THE NORTH. Laurels (Common and Portugal) and Aucuba japonica appear much injured. It is stated that for a century the thermometer has not registered so low a temperature as 15° and 16° below zero, which it has done in several places near to Newcastle.
- THE Horticultural and Botanical Society of Durham Northumberland, and Newcastle-on-Tyne held their ANNUAL MEETING on the 12th inst., the Treasurer of the Society (Councillor Gray) presiding. The Secretary (Mr. Gillespie) read his report, which was very satisfactory, the total receipts amounting to £2096 11s. 10d., including subscriptions amounting to £1188 13s. The election of officers took place, Mr. George Anthony Fenwick, Moor Lodge, Newcastle, being elected President. The Vice-Presidents were all elected again, with the addition of Mr. Lindsey Wood. Mr. Councillor J. Gray was re-elected to the post of Treasurer, which position he has filled for some years with much satisfaction to the Society.
- FROM several districts, including the North and West Bidings of Yorkshire, Lancashire, Dumfriesshire, and Derbyshire, we learn there is a general ABATEMENT OF FROST, and the snow has nearly or quite disappeared. It is too early to perceive the full effects of the severe weather, but we find that Aucubas have been killed in many places, and Portugal Laurels much injured. The thermometer at Croydon yesterday (Wednesday) morning registered 15°, or 17° below the freezing point, a dense and chilling fog prevailing.
- THAT indispensable Christmas ornament WELL-BERRIED HOLLY is abundant, but in common with other fruits the berries were much later than usual in coming to perfection. Frost set in before the colour was fully developed, and while the skin was tender caused quite two-thirds of them to turn black on many trees.

- —— On account of the cold wet season our VEITCH'S AUTUMN GIANT CAULIFLOWERS were very late. On November 6th we carefully lifted the whole batch and planted them closely together in a Peach case where frost is only excluded, and they have amply repaid our trouble, for they have given us a good succession of fine heads, and I have reason to believe we shall have plenty to last into February. I shall plant an extra quantity another season and dispense with early Broccoli, as they are so much influenced by the weather.—J. L. JONES.
- Solanum Capsicastrum, so generally grown in pots, should not be limited to that system of culture. This season, owing to a sunless summer, the plants are late and frequently bear but few berries, some only of which are coloured. We have fortunately a few planted out in odd corners of a greenhouse, and along the pathway under the stage. These are profusely covered with berries of high colour, and are a great ornament to the house, hiding as well tubs and soil. They have been of the utmost value for cutting from, and we recommend a place where this plant can grow freely year after year without renewal. It grows well against a wall.
- THAT magnificent Orchid Lælia Elegans Turneri is now flowering finely in the collection of H. Wilson, Esq., Westbrook, Sheffield. This variety is yet very rare, and Mr. Clements, the able gardener at Westbrook, considers it one of the finest Orchids in cultivation.
- The conservatory at Norris Green is looking wonderfully gay for the time of year. The side stages are "a blaze of bloom;" and the Zonal Pelargoniums in variety, which have been blooming so profusely for some time past, are still remarkably fine and produce an effect such as few winter-flowering plants can equal. These associated with early-forced Azaleas, Roman Hyacinths, Primulas in variety, late Chrysanthemums, Celosias, and many other plants, not forgetting that most useful of Orchids Cypripedium insigne, and Euphorbia jacquinizeflors, which gives to the whole a light appearance.
- —— SOME of the gayest flowers of Bromeliaceæ are to be found among the BILLBERGIAS. B. vittata macrantha is unquestionably the finest of its genus; its zebra-striped leaves are arranged in long tubes with a spreading orifice, from which depends a drooping inflorescence composed of numerous slender flowers with a light pink calyx and a tubular dark blue corolla with three recurved petals. The beauty of these is further enhanced by their orange anthers, light blue stigmas, and the showy rosy crimson bracts at their bases. It is a native of Brazil, and at present flowering in the Kew collection.
- IT was decided at a meeting held at South Kensington on Tuesday last, that the Exhibition of the NATIONAL AURICULA SOCIETY be held on April 20th, and that of the NATIONAL CARNATION AND PICOTEE SOCIETY on July 27th, both Shows to be held in the Royal Horticultural Society's Gardens at South Kensington. The Hon. Secretaries, Mr. E. S. Dodwell and Mr. James Douglas, submitted particulars of the financial affairs of the Society, which were extremely satisfactory. The Carnation and Picotee Society has a balance in hand of £21 8s. 10d., and the Auricula Society holds a balance of £12 4s. 7d. Special prizes will be offered for seedlings in all the classes, and also for species of Primulas.
- ANYONE provided with a moderately dry house with the ordinary greenhouse temperature might grow CRASSULA LACTEA. In summer it flourishes well in the open air, and in winter when housed produces its snowy panicles of minute starry flowers in profusion. Its habit is also interesting; its stout orbicular leaves being arranged in glossy green rosettes, so dense as to form a compact cushion. It is a native of the South African region where succulents abound.
- AT a meeting of the ROYAL BOTANIC SOCIETY held on Saturday, Col. Platt presiding, the Secretary reported the extremes of cold during the month. Skating in the Gardens so early in the winter has not been known for many years. Mr. G. J. Symons, F.R.S., reminded the Fellows that there had not been a warm month for two years, and that every month since August 1878 had been colder than the average. Besides being so cold the period had been characterised until the end of September 1879, by a most unusual deficiency of sunshine and excess of rain. The mean temperature of December, 1878, and January, 1879, were remarkably low, and yet the winter of 1879-Suhas begun with lower temperature than its precursor. The actual minimum temperatures in the neighbourhood of London had been surpassed in intensity on some previous occasions—for instance on Christmas day, 1860, and again on

January, 4th, 1867, the temperature of the air at Camden Square fell to 6.7°, and the Christmas day, 1870, to 14.0°, while this year the lowest point was 16.1° on the morning of Decem-The greatest severity of the late frost was, however, felt further north than London, and temperature below zeroi.e., more than 32° below freezing, had been reported from accurate instruments in many parts of the country. Mr. Symons said that most of the Fellows were probably aware how severe the weather had been on the continent. He read a letter which he had just received from a Fellow of the Meteorological Society sojourning at San Remo in the Mediterranean, who said:—"It may interest you to hear that the usually favoured shores of the Mediterranean have not escaped their share of the recent severe cold. A heavy snowstorm on December 1st has been followed by a succession of frosts of a severity unprecedented in this district. On December 2nd a thermometer by Casella registered 25° in a very sheltered part of Mentone, the snow both there and at Bordighera lying for two two days close to the edge of the sea. The gardens all along the coast are terribly disfigured, and the Olives and Lemons, both of which promised an exceptionally heavy crop, are sadly cut up. In the Mentone Valley the Lemon trees seem all but killed, and various estimates put the loss of Olives round here at half to three-quarters of the crop.'

MR. J. H. STEWARD, of 406, Strand, writesvery interesting fact that the barometer, which had been gradually rising for the past three days, reached at noon to-day (Saturday) the remarkable height of 30.79 inches, after being reduced to mean sea level and 32° Fahr. This is the highest reading since February 18th, 1873, when the recording barometer showed a maximum during the day of 30.82, and on the following morning at 8 A.M. of 30.74 inches corrected reading, which was the highest for fourteen years previously. The temperature to-day is 13° warmer than at the same hour this day week (Saturday, 6th inst.) "

BRITISH FERNS.—No. 1.

FERNS are general favourites, especially our vative species and varieties, many of which are equal in elegance to tropical forms, and it is the object of the writer in the following notes to point out such as are the most entitled to popular favour.

Adiantums.—The species A. Capillus-Veneris, or Maidenhair, is a well-known and generally admired Fern. The varieties are not numerous, the two most distinct and beautiful being

magnificum and A. aphnites.

Allosorus crispus, or Mountain Parsley Fern.—This is pretty, and in great request among the lovers of Ferns who visit its native habitat. It is very plentiful in the Lake district, and is easily distinguished by its lovely green colour. The only variety is a crested one, said to be very good, which was found

at Lethwaite by Mr. Nixon in 1874.

Aspleniums.—There are nine species—A. Adiantum nigrum, or Black Maidenhair (of which there are several varieties, but the only one I have seen worth remarking is grandiceps, a beautiful crested plant); A. fontanum, or Smooth Rock Spleenwort; A. germanicum, or Alternate-leaved Spleenwort; A. lanceolatum; A. microdon is said to be a variety of the last, but is very distinct; A. marinum, or Sea Spleenwort. I have seen several good and distinct varieties of this plant, but by far the best is the beautiful cristatum, raised I believe by Mr. Appleby of Doncaster, where I first saw it about ten years ago. a fine plant, and I was informed that fifteen guineas had been refused for it, though good plants may be now obtained for a few shillings. A. Ruta-muraria, or Wall Spleenwort—of this plant but few varieties have as yet been found; one or two crested plants have been collected. A. septentrionale, or Forked Spleenwort, not much in request except by the curious. Asplenium Trichomanes, or common Maidenhair Spleenwort, is a pretty little plant, and its varieties that we are acquainted with are very good. Cristatum and incisum, with others equally handsome and distinct, are well worthy the notice of amateur Fern-growers. A. viride, or Green Spleenwort, is a neat little plant but rather difficult to keep in health for any length of time; multifidum is the only good variety that I have seen.

Athyrium Filia-famina, or Lady Fern.—Of this the varieties are so numerous that we cannot say what the number is, but we may safely say it is not far short of five hundred; therefore we can only refer to a very limited number of the best. A. F.-f. acrocladon is very beautiful. E. J. Lowe, Esq., writing of this plant, the original in Mr. Clapham's collection at Scarborough, says "that no word picture could do justice to it." He declared it to be a mass of the most exquisite foliage in the whole range of British botany. I had the pleasure of seeing the plant at Mr. Clapham's last year, but it was much reduced by being divided, as it is a barren plant and can only be increased by division. There are but few plants in cultivation. A. F.-f. var. Craigii—we believe that we are correct in stating that this plant was first collected by Mr. Barnes of Levens, in the Lake district, and afterwards by Mr. Craig, whose name it bears, he being the first to raise it from spores and send it out to the public. It is a beautiful, distinct, and well-crested variety, and a free grower-an ornament to any collection. A. F.-f. var. crispum is a general favourite. It was collected many years ago in Ireland, and is worthy of a place in any collection of British Ferns. A. F.-f. vars. Fieldiæ and Frizelliæ, too, are distinct and attractive varieties, and being of a slender and drooping habit are well suited for suspending in baskets. A. F.-f. var. multifidum, with many others of its kindred varieties, are finely crested and numerously represented. A. F.-f. plumosum (we refer to the Yorkshire plant) is one of the most beautiful of the non-crested varieties ever collected. Mr. Stansfield was one of the gentlemen who collected it and also sent it out into the trade. It is almost membranous in texture, exquisitely divided, and—as its name implies—featherlike in appearance. There is also another variety called the Axminster plumosum. This is also a grand plant, and as it becomes more generally known must command a first-class place in any collection of British Ferns. A. F.-f. Pritchardii, another plant sent out by Messrs. Stansfield, is very pretty. A. F.-f. pulcherrimum is also a beautiful variety, and well worth growing. A. F.-f. Simpsonii is a fine plant. It has a very growing. A. F.-f. Simpsonu is a nine plant.

dense and crispy appearance, and was gathered at Hapton in Lancashire. We will conclude our remarks on this class with that beautiful plant A. F.-f. Victoriæ. This Fern has been in cultivation about sixteen years. It was gathered in Scotland, and we are not aware that a second specimen has ever been found. It is generally admired, and will always rank as a firstclass plant.

Blechnum Spicant, or common Hard Fern.-Of this species there are not less than fifty distinct varieties, some very beautiful and commercially of great value, so much so that a plant found in the Lake district was sold or exchanged for the value of £5, and is now in the possession of Mr. Barnes of Levens. It has been named by Captain Jones, paradoxum. It has three rows of pinnæ instead of two. Mr. Barnes has a fine collection of specialities. I had the pleasure of inspecting his choice and select stock twelve months ago, and I saw one form called B. trinervum coronans, plants of which he was selling at a guinea each. The following are a few others worthy of notice: —B. S. Aitkinianum, a charming variety; B. S. Maunderii is exquisitely beautiful, and only just being sent out by Messrs. Stansfield & Son; B. S. cristatum, concinnum, imbricatum, robustum, and others are very good and deserving of notice.

Botrychium Lunaria, or common Moonwort, is of no special importance to Fern-growers.

Ceterach officinarum, or common Scaly Spleenwort, is a little gem among Ferns, but one that is hard to succeed with in growing.

Cystopteris.—Fragilis, montana, and regia are the three species of this genus, but montana is by far the best. There are also several good varieties. C. Dickicana is a charming little plant and a free grower.

Gymnogramma leptophylla.—This is a small Fern, extremely pretty, and is the only annual species we have. It may be

freely raised from spores.

Hymenophyllums. - The species tunbridgense and unilaterale, or Wilson's Filmy Fern, are both attractive little Moss-like plants and worthy of a place in any fernery, but must be grown in a close and humid atmosphere if the grower wishes to see them in perfection.—J. EADON, Sheffield.

WEEKS'S PEACH HOUSE.

ANNEXED is a section and interior view of a Peach house which has recently been erected by Messrs. J. Weeks & Co. of Chelsea, in the gardens of Moor Park, Ludlow, the seat of Major Foster. The house is constructed on cast iron and slate The slate panels between the standards are foundations. about 1 inch thick, thus saving the greater part of the space usually occupied by the brick wall. The panels are also moveable, thus greatly facilitating the renewal of the border.

The lights and sashes are fitted with Weeks's improved venti-The lights and states are fitted with Weeks's improved ventilating apparatus, and the manner in which the house is constructed and planted is, we think, well worthy of notice. The rafters are placed rather further apart than is usual; and under each rafter, as may be seen by the view, is a Peach trellis, which runs across the house and forms an arch over the pathway.

The advantage of this method is, that it utilises the space and admits of a much larger number of trees being planted than is nossible under the ordinary method of forming the

than is possible under the ordinary method of forming the

trellises. Another advantage is, that the back wall is not unduly shaded, and can therefore be wired and covered with trees, which will have a fair share of sunshine. A narrow trees, which will have a fair share of sunshine. A narrow shelf runs the whole length of the house on the level of the gutter, and close to the glass, for early Strawberries. The border between the Peach trellis is utilized by growing early salads on it. Although the house has not been long finished, and the Peach trees but recently planted, they have grown well and are in a most satisfactory condition. Measrs. Weeks and

Fig. 47.-WREES'S PEACH HOUSE.

Co. have also erected similar houses in various districts which have given great satisfaction. In one which we inspected last summer, the Peach and Plum trees both on the cross-trellis and the back wall were bearing good crops, and the gardener spoke in the highest terms of the structure under his charge. Peach houses of this description combined utility with ornament in a very marked manner.

GOOD PEARS.

RANKING, as it does, as the most important of hardy descert fruits, it is not surprising that such great interest is manifested

in the Pear. During the year now approaching its close we have received communications from nearly every district in d cat Britain relative to the selection of varieties and their adaptability to various soils, localities, and modes of culture; and recognising the great number of Pears now in commerce, upwards of two hundred of which are in certain positions well described for any large of the natural that a natural tha well deserving of culture, it is only natural that a somewhat widespread desire found expression for a "Pear election." A formal election, however, would inevitably have placed many valuable Pears in false positions.

There is a fundamental difference between an election of Boses and one of Pears. The majority of those who take part

in a Rose election grow all, or nearly all, the varieties of admitted excellence; but it is very different with Pear cultivators. Out of the aggregate number who would have sent in returns only a comparative few could have made their choice from a complete collection. Pears, further, are greatly influenced by soils and situations, and a formal election would have afforded no means of disseminating information on these and kindred matters of great moment affecting the several varieties. Of more real usefulness will be a full and free dis-

cussion of the merits and demerits of Pears of admitted repute in different districts and under conditions that can be named. In order to elicit information of practical value we propose from time to time to submit engravings of good Pears with the object of concentrating attention on them, and of others repening at or about the same period. The figures to be given are of such fruits that we could obtain during the present unare of such fruits that we could obtain during the present unare of such fruits that we could obtain during the present unare of such fruits that we could obtain during the present unare of such fruits that we could obtain during the present unafavourable season. They will be represented as they were gathered from the trees, and will be truthful portraits of the

Fig. 48,-WILLIAMS' BON CHRETTEN PRAR.

varieties produced under ordinary cultivation rather than as showy specimens selected from dishes on the exhibition table.

Assuming that the variety figured, which is one of the best known of all Pears, ripens about the end of August during fine seasons in the southern counties (for it varies according to seasons and localities), it will be well to consider which are the most useful Pears that precede it; and also in what soils and localities and under what conditions Williams' Bon Chrêtien falls to produce satisfactory fruit, and where and how it succeeds best.

Of the July Pears three may be named—the Amiré Joannet, or Harvest Pear; the Petit Muscat, or Small Cluster Pear; and the Doyenné d'Eté, or Summer Doyenné Pear. As in the majority of collections only one of the three will be required,

the question follows, Which is the most useful? If more than one are wanted place the three in order of merit, naming the forms and conditions under which they give the best results.

August Pears are more numerous. Some of the best and

August Pears are more numerous. Some of the best and most useful are the Jargonelle, Citron des Carmes, Bloodgood, Désiré Cornelis, Summer Rose, Beurré Giffard, Beurré Précoce, Souvenir du Congrès, and Beurré de l'Assomption. Information relative to these varieties, gained from experience of them in different districts, would be of service to many.

There are many growers of Pears who are able to contribute a small, but it may be a very useful, mite of information on the varieties, or some of them, we have named, who are not prepared to submit a selection of Pears from a large and complete collection; or they may possibly be able to name as worthy of culture other varieties in what we may call this

August list, although in some localities the varieties named

may not ripen until September.

Of the old favourite figured we may observe that it was raised upwards of a century ago by Mr. Wheeler, a school-master at Aldermaston in Berkshire, and was named by Mr. Williams, a nurseryman at Turnham Green, who distributed it. Our experience of this popular Pear is that in light soils in the southern counties, and in warm localities generally, it is an excellent variety for the north aspect of a wall. If grown in the full sun it ripens on the tree, its full flavour is not developed, and it is over in a few days. In stronger soils and cooler positions over a great extent of the country it succeeds as espaliers, pyramids, and standards. In more northerly and cold districts the shelter of a wall becomes of advantage, yet it is a very hardy and good grower, and if not a prodigious bearer it is fairly productive, and is altogether a very valuable Pear. What do others say about it?

Pear. What do others say about it?
Fruit of Williams' Bon Chrêtien is sold annually by tons in the streets of London under the name of "William Pears," a name that is familiar to almost every schoolboy in the metropolis.

In communicating experience on Pears it will be additionally valuable if the nature of the soil and subsoil are stated; on what stocks the trees are grown or succeed best; the district, and its approximate height above sea level, with the average rainfall; if on walls, state the aspect; if in the open, whether sheltered by adjacent walls or distant hills or woods. Local conditions, which by long familiarity may appear trivial to the casual observer, exert much influence on Pears, therefore circumstances of the nature indicated should not be overlooked by those contributing information on this important subject.

Letters to insure insertion next week should arrive at this office on Saturday.

COST OF EXHIBITING ROSES.

I would advise all aspirants to Rose-exhibiting to first weigh well the cost, and not to decide to enter on the campaign without serious reflection and much thought. I do not wish to dissuade anyone from exhibiting; my wish, on the contrary, is that many more would join us, and that each year should see the number of exhibitors increased, but I wish to save amateurs from disappointment, and, I may add, serious pecuniary loss. It is, then, in the most unselfish spirit that I give this advice. A man, then, who would be a successful exhibitor must be one who can afford to spend a considerable sum of money in the pursuit of his hobby.

If I am asked to name a sum which a rosarian should be prepared to spend on this pursuit, I hesitate not unnaturally from doing so, as I know full well the amount of dissent and discussion that such a statement would create, yet I will venture to name a sum. I do not, then, think that any person who wishes to show thirty-six distinct varieties, to say nothing of forty-eight, can hope to do so unless he is prepared to spend £100 on Roses, and the expenses incidental to their culture and exhibition. And this I maintain is a reasonable estimate,

and I will try to prove that it is so.

(1.) A man who wishes to show thirty-six distinct varieties of Roses should at least grow sixty sorts. Why? Because on no given day could he depend upon having a good bloom fit for exhibition of thirty-six Roses if he confined himself to this number. Some Roses bloom much earlier than others. Monsieur Noman will be grand for the early Crystal Palace Show, but will be quite over for Hereford or Manchester. Teas, again, are rarely of use for the July shows, but are the greatest help in June. Marie Rady is glorious in July, but rarely in bloom about midsummer. He must, then, have at least sixty sorts, and (2ndly) he must possess twenty plants of each sort. No less number will suffice; and when I say that some of the great amateur exhibitors possess from two to three hundred of the leading sorts, I think it will be granted that twenty is a very small number indeed. This will give him 1200 plants, the cost of which may be put down at (including Teas) £60 if they are on the Manetti or seedling Briar, or £90 if they are standards.

It will be seen at once that if standards are purchased, £100 would be quite inadequate for his purpose. But supposing dwarfs are purchased, and most exhibitors rely on them for their best blooms (I do not wish to mention names, or I could cite two of the leading amateurs who have not a standard in their possession), £40 would be left. Of this £20 must be spent on manure. Of course the cost of manure depends in a

great measure upon the neighbourhood in which the exhibitor lives, but here I have to give £1 for every load of manure—i.e., 10s. for the manure, and 10s. for the handling; and on my small churchyard alone I have this year spent £24 in manure. There is not only to be considered the manure required to dress the land in autumn, but also the spring surface dressing and the liquid manure in the summer.

£20 is, if anything, too small a sum to be spent on 1200 Roses, but I wish to put everything as low as possible. There remains, then, only £20 for all the expenses of exhibiting the blooms. This may appear ample at a first glance, but is it too much? By no means. Let the exhibitor remember that he has to take his blooms by rail and road to such a place as the Crystal Palace; that if he has a large collection he must take his gardener with him; that he has expenses at all the junctions where he has to change, or if he is on a main line he has expenses at both ends. Then there is his own expenses and his man's, and when he arrives in London he must either take a conveyance direct to the Palace, which will cost him about 30s., including the driver, or he must take a cab to one of the railway stations, and go by train, and undergo the same expense again. I never showed Roses at the Crystal Palace at a less expense than £5, and I travel second and my man third class. Supposing, then, he shows at the Crystal and Alexandra Palaces, and Hereford and South Kensington, he will find that these four shows cost him £20. Against this there is the chance of prizes, but it is better not to reckon too much on them.

Next, exhibiting is somewhat selfish, and, unless the exhibitor is a bachelor, the cause of much bickering and heartburning. The plants have to be kept entirely reserved for the shows. No one must pluck a bloom, however near and dear she may be. Most extensive disbudding takes place. The plant is only allowed to grow three or four blooms, so that all the strength of the plant is thrown into those blooms. As often as possible the plants have to be drenched with the strongest liquid manure, and the smell from this stuff is quite frightful to delicate nostrils. Plants must be shaded in scorching weather, and the shades removed at night. The labour during the monits of May, June, and early in July must be most assiduous, and the care and anxiety expended on the plants almost overwhelming.

There is always the danger of overdoing the stimulants; the guano may be put on too heavily by the man you put so much trust in, and the plants are burnt up and destroyed; or the foliage may be syringed on a June evening, when a sharp frost ensues, and cuts the foliage as if a hot iron had been over it.

. All these and many other things should be considered by the would-be exhibitor, and if, after well weighing them, he finds that he is still eager to try his hand at exhibiting, by all means let him go in and win.

THE above is the article cited from Mr. William Paul's "Rose Annual" that a correspondent, "Duckwing" (page 439) has thought fit to criticise, and in courteous language to condemn. I have delayed answering the stricture referred to until my article appeared in the Journal.

The case stands thus: A correspondent perfectly unknown to me has caused to appear in what is often called the Rose Journal, a letter which contradicts all that I, who have been before the Rose public for many years, have written upon the subject, with which I am better acquainted than any other. All I write on the subject of Roses is the result of long experience, and I never make any statement which I have not proved to be true.

"DUCKWING," however, simply contents himself with denying all I state. He gives no reasons, adduces no arguments, simply gives his *ipse diwit*, as if that was quite enough. Looking through his article I find that he gives advice so dismetrically opposite to my own that I really do not know where to begin my refutation. Perhaps I had better discuss his statements in the order in which they appear.

First, "DUCKWING" assumes that I advise people to begin showing in nine months from this time at the great metropolitan shows. It was necessary for me to make mention of the shows which the would-be exhibitor would frequent, but I say nothing as to when he should begin. Your correspondent says that unless Roses behave very differently in his soil than they do in mine any attempt to cut a good box from Roses bought the first year will only prove a failure. Now my experience is totally opposed to his. All the prizes that I have won have been gained by Roses purchased the autumn before the shows. He also says that it would be absurd for an exhibitor to compete the first year at the great London and provincial shows.

that he must for a few years be content to show at small country exhibitions in his own neighbourhood. Must he? Well, I do not want to boast—I have never done so; but in justice to myself I am bound to add that the first year I showed Boses I went to the great exhibitions; that I was only defeated by Mr. Baker at Exeter, and that the next year I showed in two classes only at the Crystal Palace (36 and 24), where the competition was unusually great, and was first in both. So much for "DUCKWING" on these two great points. Mr. Jowitt was equally successful; he jumped to the first rank during the was of his dibbat

year of his debat.

"DUCKWING" also calls in question all I say on the culture of the Rose. He disputes my figures, ridicules my estimate of the cost of manure, and disputes every statement I make. It would be too wearisome to your readers were I to go in to the question of the cost of Roses, for I write from an entirely different standpoint from "DUCKWING." He speaks of budding one's own Roses, and waiting a twelvemonth before a man shows a Rose. I advise cutbacks, and showing the next year. The cost is, of course, more; but it is far more gratifying to amateurs to have Roses at once than to have to wait for twelve months looking at stocks, to find that after all his labour and care 25 per cent. have not struck, 25 per cent. have been blown out, and the rest are poor miserable "ducklinga," which require the greatest care before they cast him a good feather.

In conclusion I have to state that my article was not written for the Journal, and was not by me deemed suitable for the Journal's columns. The Journal may be taken to be inter alia the official paper of the exhibitor of Roses. A paper, therefore, written with the express object of warning young Rosegrowers who may be intending to become exhibitors that they had better reckon the cost before they begin would, I thought, not be the kind of paper to suit the Rose Journal. With Mr. William Paul it is quite another thing. He represents the greatest non-exhibiting Rose-growing firm with which I am acquainted; and a paper written with the above-named object was most gratifying to him. He particularly requested me to writte for him; I did so entirely as a friend, and I never contemplated for one moment that anyone would discuss my letter in the Journal of Horticulture.—WYLD SAVAGE.

SURELY "DUCKWING'S" reduced estimate of the expense of Rose-exhibiting is too high, and as I fancy some would-be exhibitors may be deterred by fear of expense I venture to send you my experience of the subject. For some years I have exhibited with fair success, though my maximum number of Roses has never exceeded five hundred. I bud yearly one hundred or thereabouts, and discard all old plants that are not doing well; but then I never attempt more than a twelve, or, if there should be such a class, six trebles. This requires three, or at the most four 12-boxes, which cost about 12s. 6d. each; tubes, 2s. 6d. a dozen. I never manure at planting time, but mulch with pig manure in the early spring. Last year I put on thirteen cartloads at 6s. per load, and this afforded a mulch some 5 or 6 inches in depth to about five hundred plants. How "Duckwing" or any other man can dispose of £20 worth of manure on 1200 Roses exceeds my comprehension.

As to Roses planted in the autumn, my experience is quite contrary to that of "Duckwing." Roses planted last autumn afforded me many prize blooms, including the premier bloom at one good local show and the second best bloom at another. From Roses planted in the spring I also cut a good box of twelve of one variety (Marie Baumann) with a little assistance from Briar maidens. In all, last year I was indebted for help in fourteen prizes to Roses planted in the autumn and spring. Certainly last year was favourable to newly planted Roses jibut it has been my practice for years to transplant Roses budded on the Briar while still dormant, and this year I have adopted a similar course with those budded on the Manetti. I have never tried this before, so the success or failure of the attempt is yet to be proved. I quite agree with "Duckwing" in one respect—viz., that nothing but experience will teach the perhaps most necessary point of all—i.e., the stage of growth in which to cut different varieties for exhibition, how to carry them to the show, and how to set them up.—Kentish

THE SEASON IN DUMFRIESSHIRE,—We had our share of the hard winter of 1878-79, and occasionally frosty nights until the 27th of May, when we had 3° of frost, and on the

5th of June 1°. We escaped frost in July, but on the morning of the 26th of August the mercury was 3° below the freezing point, when French Beans and many tender bedding plants were blackened. On the 21st of September and 7th of October it fell to 5°. On the 21st of November we had 4 inches of snow, and on the 24th, 29th, and 30th of the same month the mercury registered 11° below the freezing point. On December 1st, 11°; 2nd, 21°; 3rd, 20°; 4th, 28°; 5th, 26°: 6th, 20°; 7th, 11°; 8th, 18°; 9th, 10°; 10th, 9°; 11th, 18°. As will be seen from the above, July is the only month that we have escaped frost during 1879. Strawberry plants seem to have suffered very much from the late cold frosty winds. The hardest frost we had here in 1878 was on the morning of the 13th December, when the thermometer indicated 2° below zero. At present we have every appearance of having a hard winter, and I am afraid that vegetation will not stand it so well this season as last. Owing to the wet summer, trees, shrubs, &cc., are not so well ripened.—JAMES DECESON, Arkleton.

BRYNKINALT,

THE SEAT OF LORD HILL TREVOR.

BRYNKINALT is situated about two miles from Chirk station and about twenty miles from Chester, and is reached by rail from that city. The estate is an extensive one and the gardens are large. The park is of great magnitude. The surroundings of the mansion are picturesque, being andulated and well wooded. Especially noteworthy are the trees in the park, which have been either thinly planted or timely thinned, and have developed into grand specimens.

The mansion is reached by a winding drive leading through the park from the village of Chirk, and is about a mile and a half in length; it is also approached by another main drive from Brynwillan near St. Martin's, which is about two miles in length. This we believe to be the most picturesque, leading as it does through a hilly district and avenues of fine Oaks. The mansion stands on an elevated site, and covers an acre of ground. It is a noble and imposing structure, and has been built at different times. The oldest portion was erected in 1609. Fine additions have been made of more recent date until it attained its present size. Close in the valley below is a small rippling stream winding its course with much beauty, and adds materially to the view from the mansion.

The pleasure grounds are elaborate, varied, and comprise about twenty acres. There are three flower gardens in different parts of the grounds and of entirely different designs. The one on the west of the mansion was laid out by Charlotte Viscountess Dunganon in the year 1808, as well as the surrounding grounds. This is employed for subtropical bedding, which this year has proved anything but satisfactory in consequence of the extremely inclement season. The principal flower garden is some distance from the Hall. The design of the garden is a scroll pattern on each side of the walk, with large circular beds in the centre, with beds of the Shamrock pattern round them. The bedding, when we visited the garden in late summer, was very creditable, there being an even balance of beds of flowering plants and others devoted to carpet bedding. A very fine border of Roses with a Peach wall at the back attracted notice. The Peach trees were good and well trained, carrying a fair crop of fruit ripening much better than we could have anticipated. This border contained a fine row of Tritoma Uvaria grandiflora, producing thousands of brilliant spikes, which were very striking. We next passed between two large ribbon borders, the front portion of which was planted with the usual flowering plants, and one row of Dell's dark-leaved Beet on each side, which contrasted admirably. The two most striking rows were at the back, one being composed of Hollyhocks of different shades free from disease, and Sunflowers planted alternately. The other row was composed of Phloxes of different varieties alternately planted with Dahlias, the effect being gorgeous. These borders lead direct to the main range of houses. The number of bedding plants required is ninety thousand, and the accommodation to grow them is most limited.

The glass structures are not extensive: they are nine in number and mostly heated with flues, with the exception of the greenhouse. There are three vineries, in all about 104 feet long and 14 feet wide. Some of the Vines are old, while others are young, none of which are in the most vigorous condition owing to the heavy crops they have previously produced. The fernery contained clean well-grown plants. The Cucumber house was planted for winter work, and the stove was well

filled with plants of a suitable size for table and other decorative purposes, no attempt being made to grow specimens; the plants were clean, healthy, and in capital order. The green-house is devoted to growing flowering plants for cutting, and to furnish the verandah, which is situated at the front door of the mansion, and is kept gay with seasonable flowering plants. The conservatory also joins the mansion and is principally

planted with Camellias.

The kitchen garden is a walled enclosure 7 acres in extent. It is divided in the centre where the houses are situated. The garden is square, having a walk all round, and borders next to the wall 16 feet wide. It is divided into a number of squares by cross walks; the walls are covered with well-trained trees in good bearing condition. The ground was clean and well cropped, containing large breadths of Savoys, Brussels Sprouts, and Broccoli of sorts—thousands of such varieties as Snow's Winter White, Veitch's Self-protecting, and Autumn Giant. Suttons' Late Queen Broccoli was worthy of special note on account of its compact and dwarf nature; other late kinds and winter vegetables generally were also planted in quantity.

The Rose garden merits brief notice. It is on the north of the mansion, and is sunk some 21 feet below the surrounding ground level, the design being a scroll pattern and Shamrock-shaped beds planted with standard Roses, the vacant places and groundwork being filled with Mignonette and other similar plants. In the centre is a large circular trellis and Roses trained upon it. This, and the surrounding grounds were laid out by the present owner. The gardens in all departments were in admirable condition. They were at the time of our visit under the charge of Mr. W. Cook, who, we regret to hear, has since resigned his position, but we trust he will soon meet with a charge of Mr. W. meet with a charge equal to his abilities .- B. N. G., a Visitor.

THE EFFECT OF FROST ON HARDY FRUIT TREES.

Mr. WITHERSPOON, on page 462, attributes the general failure of the hardy fruit crops this year to the severe weather of last winter, and appears as if he rather desired someone to differ from him in his theory. I will try and oblige your correspondent, but on the express understanding that my remarks will apply to fruit trees generally, and not to Mr. Wither-spoon's exclusively. If the pith of the fruit trees referred to was blackened by the frost, that is quite sufficient to account for their barrenness, for when the wood of the spurs is in that state I take it to be impossible that they can support the fruit that may even apparently set after the flowering period. An exposed and northerly position has unfortunately more than once afforded me an opportunity of observing the results of trees frozen in the manner indicated, and I never knew fruit to follow injury so extreme. So far I agree with Mr. Witherspoon; but when he suggests that the loss of the crops generally is attributable to frost in winter I am bound to differ from him. But before I state my reasons for so doing, I may observe that your correspondent omitted to state that the wood of the trees of Marie Louise d'Uccle that produced fruit was not injured like the others. No doubt it escaped being blackened at the core, but it would have been well had the fact, if it is a fact, been stated.

I will now refer to another kind of blackening that is equally fatal to the fruit crops, and much more common—namely, the blackening of the core of the blossoms by spring frosts. If on examining the ovary of the blossoms after a severe spring frost a small black speck is found, no fruit can follow. I examined the wood of hundreds of spurs of fruit trees last April and May which were certainly not black at the pith, yet not one fruit followed on many of the trees. It was not the winter's frost that rendered the trees fruitless. If Mr. Witherspoon's theory is correct, and applying it generally, there ought to have been plenty of fruit in the south of England this year, where the frost of last winter was not sufficient to freeze the pith and blacken it, and yet if what we read is correct, the Apple and Pear crops have been about as scant in Kent as in Yorkshire and Durham. But, further, Mr. Witherspoon must remember that the winters of 1877 and 1876 were not severe, yet in the summers following fruit was about as scarce as it has been this year. In the years mentioned, spring not winter frosts destroyed the crops; but the loss of the crops this year was primarily caused by excessive wet during the flowering period. So continuous was the rain that pollen never formed on many trees that I watched very closely, and fertilisation became an impossibility; the showers of hail and rain were so heavy, too, that the blossoms were dashed from the trees even

before expansion, and the ground was quite white with mutilated petals. Your correspondent thinks the rain "may" have been detrimental, but I assert that it was positively destructive. Neither does it follow that the injury by excessive wet and frost in spring should affect all trees alike, any more than frost in winter has the same effects on all trees. Varieties vary much in the hardiness of their blossoms, and further, all do not expand exactly at the same time, and hence the different results. Many good cultivators have also attributed the dearth of fruit in a great measure to immature wood, and I have observed more than once that when young and luxuriantly growing trees blossom freely fruit does not follow with the same certainty that it does on trees which have produced shorter growth that has been harder and better ripened. Various causes conspire to render fruit trees barren, and extreme frost in winter as described on the page quoted is one of them; but it has neither been the sole nor the chief cause of the general absence of fruit during the past four years, simply because there has been no such severe frost except in certain very cold districts, and during two of the years the winters were mild as the Americans say, "all along the line." Applied generally, therefore, over a wide district, and over a period including mild winters when little or no fruit followed, Mr. Witherspoon's theory fails .-- A NORTHERN GARDENER.

NOTES FROM IRELAND.

WINTER is now upon us, and great vigilance is required in tending plants under glass. We have experienced twelve days' trost of great severity. The following number of degrees below the freezing point were registered:—November 30th, 14°; De-cember 1st, 17°; 2nd, 24°; 3rd, 8°; 4th, 27°; 5th, 33°; 6th, 3°; 7th, 19°; 8th, 16°: 9th, 15°; 10th, 19°; 11th, 16°; 12th, 6°. On the 2nd of this mouth we had a fall of about 6 inches of snow; at the time of writing about 2 inches remain on the ground. A thaw took place on the 10th, and we were in hopes of less severe weather, but that evening the mercury fell 16°. We commented in a previous letter on the unsatis factory state of the bog turf used in this locality as the chief fuel, and although we experienced six weeks of delightful autumn weather the want of drying winds left it in much the same condition, so that stoking with turf has been no easy matter. Those having an abundant supply of coal may well feel that their lots have fallen in pleasant places. Previously to the 29th of November we had but little frost. A large number of Chrysanthemums planted out of doors, which want of accommodation deterred us from potting, expanded a considerable number of good blooms. The best were Fingal, Hermione, Empress of India, Princess of Teck, and Aurea Multiflors. As we anticipated, Apples and Pears as regards keeping and flavour have been quite a failure. It may be of interest to add that on the farm here several acres of the Scotch Champion Potato grown this season have given much satisfaction; having been entirely free from disease they contrasted with other varieties which have suffered terribly. The year 1879 will not varieties which have suffered terribly. The year 1879 will not be readily forgotten in this country either by the gardening or the farming fraternity.-R. BLACKSTOCK, King's County.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Forcing Department.—The chief difficulty in this department in severe weather is to prevent Radishes, Carrots, &c., from becoming tall and weakly, owing to their being kept close and covered up to exclude frost, the heat from the bed and linings causing rapid growth. This should be guarded against as much as possible by employing no more protective material than is absolutely necessary to exclude frost, and withdraw the covering as soon as necessary to exclude frost, and withdraw the covering as soon as possible, ventilating the frame when the weather is favourable. Potatoes also should have all the light and air possible, lining the beds as may be necessary, and protecting with mats or other material so as to exclude frost. Continue to prepare well-fermented materials, to be employed in making up beds for successional Potatoes, Radishes, Carrots, Lettuces, and Canlidowers. Continue to introduce roots of Seakale, Rhubarb, and Chicary to the Mushroom house, maintaining the heat of Asparsgus beds by additional linings. A successional bed will require to be made, and when ready fresh roots should be planted to keep up the supply. Continue to sow seeds of Mustard, Cress, &c., for small salad, which is generally in request at this season. Place in a vinery in pots or boxes a few more roots of Mint and Tarragon. Water Rhubarb, Seakale, and Chicory liberally with warm weak liquid manure after they commence growth. Where Peas have not been sown in autumn preparation should now be made for not been sown in autumn preparation should now be made for

sowing them under glass, either in cold pits, a late Peach house, or orchard house. The old-fashioned horseshoe draining tiles. 3 inches in diameter, answer, or troughs of wood may be used but where turf can be obtained and cut into strips about 4 inches wide and 3 inches thick, it forms the best material. The strips should have a groove cut down the centre half the depth of the turf, the seed being sown and covered at out 11 inch deep. When the Peas are 4 inches high the turves may be carried out and placed in drills prepared to receive them on a warm border, mild weather being chosen.

FRUIT HOUSES.

Cherry House.—To insure a supply of ripe Cherries from the middle of April and onwards houses which are to be advanced by forcing for this purpose should now be closed. Be sparing of fire heat at the commencement, not employing it unless absolutely necessary to maintain the temperature at from 35° to 40° at night, and 40° to 45° by day, ventilating when the temperature is about 50° or 55°. Close the house at 50°. Syringe the trees and available surfaces early on fine afternoons, so as to admit of the buds becoming dry before nightfall. Plum trees in pots in this structure require similar treatment to Cherries.

Vines.—Aftention should be given to the fermenting material in pits containing early Vines in pots, and if the pots are placed on pillars frequent additions of material may be made as the heat declines. The temperature should have been raised gradually after the buds commenced swelling from 55°, so as to have it about 60° or 65° by the time they are coming into leaf, allowing an advance of 5° to 10° by day, carefully admitting a little air at 70°. Disbud as soon as the bunches can be detected, reserving the most promising. Stop the laterals about two joints beyond the bunches. Where fermenting materials are employed the necessity for the application of moisture will not be so great as where the heat is obtained solely from hot-water pipes. Evaporawhere the heat is obtained solely from hot-water pipes. Evaporation troughs should be filled with liquid manure composed of 1 th. guano to twenty gallons of water, which may also be employed for damping the floors, &c., early in the afternoon after closing the house. The buds of the Vines in the early house now show signs of swelling, and another good watering should be given the inside border at a temperature of 85° to 90°, and in the case of old Vines liquid manure should be freely applied. From the time the buds commence swelling the temperature should be raised 2° or 5° in the course of a few days not exceeding 60° to 65° to 70°. buds commence swelling the temperature should be raised 2° or 5° in the course of a few days, not exceeding 60° to 65° by artificial means until the Vines have produced their leaves. In quick forcing, and where the Vines are thoroughly established and have had a long rest, growth may be induced by a brisk moist heat of 70° to 75°, continuing it until the eyes have fairly started growing, when the temperature should be allowed to fall to 65° or 60°, with 5° or 10° rise in the daytime, it being important whilst the foliage is being made that a moderate temperature. foliage is being made that a moderate temperature be employed, in order to secure short-jointed wood and well-developed leathery foliage. Young Vines that have not been forced early will need to be brought down to a horizontal position to ensure their breaking regularly. Some well-fermented short stable manure and leaves placed in ridges on the inside borders will afford a genial moisture and warmth, and lessen the necessity for frequent syringing. See that the fermenting materials on outside borders are not cooled by snow melting on them, and lose no opportunity of turning and adding fresh material as may be required. Push forward the pruning, dressing, and cleaning of Vines in succession houses, a complete and long rest being conducive to a regular and strong break when the time arrives for starting. Late Vines that have the foliage all off will only require sufficient fire heat to exclude frost; even a temperature of 50° in sharp weather dries the atmosphere too much to preserve thin-skinned Grapes, such as Muscats and Black Hamburgh; 40° to 45° is sufficient, keeping the house closed in damp weather, and seeking to ensure a dry, cool, and equable atmosphere.

Orchard House.—The trees in the house should before this have

been placed close together and the roots protected by a covering of dry litter or fern, or if they have become frosted before this were done it should still be performed, so that they may be graduwere done it should still be performed, so that they may be gradually thawed. The trees outside plunged in ashes and protected with cocoa refuse will be quite safe. The house should have a thorough cleaning when the weather is suitable in readiness for bringing the trees in early in the new year, or if the house can be prepared sooner they may be housed at once, protecting the roots of the trees with dry material. In bright and mild weather the house should be freely ventilated.

Strawberries in Pots.-When the crowns commence swelling and the trusses appear the temperature may be advanced a few degrees by day. A temperature of 50° to 55° is sufficiently high degrees by day. A temperature of 50° to 55° is sufficiently high at night. Syringing the plants gently in the early part of bright afternoons will be advantageous. Examine the plants daily, and supply water to all those that require it. Keep a sharp look-out for aphides, and if any appear fumigate the house on two consecutive evenings. Another batch of plants should be placed in a house from which frost is excluded, the decayed leaves being removed, and the surface soil loosened and top-dressed with horse droppings rubbed through the hands. The dramage should be attended to and if necessary rectified and the pots washed clean.

The plants may be introduced during the next three weeks to a Peach house or to a Strawberry house if such be available, follow-ing the instructions given in a former calendar. Sir Harry, La Grosse Sucrée, and President, with Vicomesse Hericart de Thury are suitable varieties. Plants for introducing later on will be quite safe in their quarters outdoors plunged in ashes to the rim, and a light covering may be given of dry fern or litter, removing it in dry weather.

FLOWER GARDEN.

Bedding Plants.—Zonal Pelargoniums and others will require to be examined frequently for the removal of bad leaves and decayed shoots, watering them early in the day should any of the plants require it. Over-watering, however, should be as much avoided as over-dryness, and they should have a temperature of 40° to 45°. Bronze, Gold, and Silver variegated, with tricolor varieties, require a temperature of 45° to 50° to maintain them in good constitutes. dition. Petunias, Verbenas, Heliotropes, &c., should be sparingly watered, the foliage, however, being kept fresh, and a temperature watered, the foliage, however, being kept fresh, and a temperature of 40° to 45° being suitable, ventilating freely whenever the weather is favourable. Coleuses, Iresines, and Alternantheras should be placed near the glass and have a temperature of 55° to 65°. Succulent plants should be kept dry. Plants in cold frames and pits, such as Calceolarias, must be well protected with a good thickness of straw or fern in addition to the mats. Compost for spring propagating and potting should be placed under cover without delay so as to have it in suitable condition for the nurpose when delay, so as to have it in suitable condition for the purpose when the busy time arrives. Turfy loam with the turf reduced will be needed in greatest quantity, and after that well-reduced leaf soil or decomposed manure. Potsherds may also be prepared; it is sand, in many respects preferable to silver sand for propagating purposes, though for fine seeds a stock of silver sand must be

PLANT HOUSES.

Store.-Many growers of stove plants adhere to the practice of plunging the pots in some fermenting material such as tan or leaves, or where hot-water pipes are employed to furnish bottom heat cocca-nut fibre refuse is generally used for plunging the pots in. Except for a few species after potting, bottom heat is not necessary to the successful cultivation of stove plants. The chief objection to plunging is that the plants must necessarily be at a distance from the glass, resulting in the growth made being always more or less weak, and the plants are so much more tender when more or less weak, and the plants are so much more tender when grown in bottom heat than when placed so that their tops almost touch the glass. Whether the plants are required for exhibition, conservatory decoration in summer, or for the production of flowers for cutting, they are not in the former case nearly so valuable. Although bottom heat is neither necessary nor advisable, yet a good bed of fermenting material some 4 feet thick is of the greatest service in producing a genial temperature and moisture, and a bed of this kind will maintain a heat of 90° or more for two or three months, besides being conducive to a free healthy growth. Tan is unquestionably the best material, but where that is difficult to obtain clean Oak or Beech leaves form good substitutes. Plants that shed all or a portion of their leaves, such as Clerodendron Balfourianum, Bougainvillea glabra, &c., should now for some weeks only receive as much water as will keep the remaining leaves from shrivelling. In order to induce as complete a rest as possible a temperature of 55° should only be accorded them. Evergreen plants should have sufficient water to maintain the foliography and the sufficient water to maintain the foliage in good condition, but water at this season should be sparingly supplied.

TRADE CATALOGUES RECEIVED.

Walter Charles Slocock, Woking .- Catalogue of Conifera, Roses,

William Farren, How House, Cambridge.—List of Roses.
E. André Leroy & Co., Angers, France.—Catalogue of Vegetable and Flower Seeds.

F. C. Pomrencke, Altona.—List of Bulbs.

TO CORRESPONDENTS.

* All correspondence should be directed either to "The Editors' or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We sannot reply to questions through the post, and we do not undertake to return rejected communications.

BOOKS (W.C.).—We are not acquainted with any work such as you appear to require, (D.B.).—You will find the native countries of the plants enu-

meratel in the "Cottage Gardeners' Dictionary," and the dates of their introduction to this country. The price of the book is 6s. 6d.; post free from this office, 7s. 2d.

SCENTLESS ROSES (Surger).—You will find a list of Roses that have little or no perfume on page 198 of our issue of September 4th of the present year. If you do not possess that number you can obtain it by sending 3½d. in stamps to the publisher, requesting him to send you No. 962. Pears or Plums, or both, would succeed well on the wall where Peach trees are not satisfactory.

PERFORATED POTS (J. Gilchrist).—The perforated pots figured on page 447 can be made by any potter; the holes should be ordered before the pots are hardened. Mr. Rivers, we think, obtains his pots from Mr. Lewis John Walker, Wood Green, Waltham Abbey.

VALLOTAS DECATING (S. P.).—The bulb was completely crushed in transit through the post. If you send us another in a small box it shall be forwarded to the gardener whose instructions you have followed. We do not, however, think the spider you name has caused the decay.

STORING POTATOES (J. 8.).—The mode you suggest will answer provided the tubers are sufficiently covered to exclude frost; but they should not remain in the bags a day after signs of growth are apparent, but should then be spread thinly in a cool and if possible a light place; the shoots will then grow slowly, and be of that sturdy character which is so serviceable for securing good crops. Very thick coverings of straw or other light and dry material will be necessary for the safety of the tubers if the present severe weather continues. The quality of the Kale is generally better when the leaves are cut off a short distance from the stem than when torn off roughly.

RARLY APPLES FOR EXPOSED POSITION (Idem).—Dessert: Early Julien, Devoushire Quarrenden, and Ravelston Pippin. Kitchen: Carlisle Codlin, Lord Suffield and Keswick Codlin.

BPSOM SALTS AS MANURE (W. K.).—This substance, sulphate of magnesia, is an excellent manure, and you may safely apply it to your lawn and garden crops at the rate of 3 or 4 ozs. per square yard.

BRIARS (J. B.).—We have considered your question, and do not feel justified in stating the purport of it to our correspondent to whom you refer.

ERICAS IN COLD PIT (A Reader).—It is impossible for us to say whether the injury your plants have received is sufficient to cause their destruction. Thousands of Ericas are wintered in unheated pits, but they are well protected, and even a few degrees of frost will not kill the hardier species, but it often browns and disfigures them. Do not remove your plants to a warm house, but keep them as cool as possible consistently with the frost being excluded, and you will adopt the best mode of mitigating any injury the plants have received.

plants have received.

CHRYSANTHEMUMS AFTER FLOWERING (Sol).—We presume that your Chrysanthemums are grown in pots under glass; if so, we should cut them down level with the surface of the pots immediately they have done thewring in order to encourage cuttings for reproducing the stock for another year. If your plants are growing out of doors the first favourable opportunity should be chosen for cutting them down, and some well-decayed manure forked in around them. They will in that case form large clumps for next autumn.

BOBES IN POTS (Granville).—Successful growers of Roses in pots repot them every year, not necessarily in larger pots if the plants are already large and the accommodation for growing them limited, but that they may make new roots, and receive a greater amount of good food during the summer that is so essential for producing fine flowers in the following spring. The best time for potting Roses is in the month of June directly after they have finished blooming, using a compost of two-thirds of good turfy loam and a third of well-decayed manure. Tea Roses having the addition of a little leaf soil and sand. By repotting them at that period the new roots take kindly to the soil, which enables the plants to make good growths early, that become hard and ripe before the summer is ended. After potting they should be plunged in an open situation, and a third conting of manure placed around and over the surface of the pots, so that the roots are kept cool, and the rains wash in the properties of the manure. Roses in pots are often spoiled through neglect during the summer, which is the season they should receive the most attention. You would not reap much benefit by repotting now; the better plan would be to losen and remove a portion of the surface will and apply a top-dressing of rich compost. Prune the plants during this month and the next, the the points of the shoots downwards, and allow them to break very steadily and without any assistance from fire heat. They may possibly break back from the old wood. As they advance in growth a slight sprinkling of blood manure over the surface of the soil will strengthen them, using a solution of cow manure and soot as the flower buds advance.

PRUNING OLD PEAR TREES (A. B. C.).—It is questionable if root-pruning would render the trees fruitful. If a great number of the spurs were removed, and some of the branches too if crowded, and young growths were trained thinly to the wall and sufficiently exposed to the sun to ripen their wood, they would in due time form fruit spurs the same as the young wood does at the extremittee of the branches.

ZONAL PELARGONIUMS IN POTS (Id-m).—In all probability you will find on turning the plants out of their pots that the roots are not in a strong active growing state. In this case we should remove a portion of the old soil from them and repot in clean well-drained pots of the same size, and encourage growth by placing the plants in a light position in a house having a minimum temperature of 45% to 50% tresh roots would then form speedily, and as soon as these protruded through the pots we should repot as you propose. You may remove the old soil and apply fresh about February, or whenever you can ensure a genial temperature for growing on the plants without check. Do not tie them down too soon.

VINE (E. F.).—We do not know a Grape under the name you submit. The largest black Grape is Gros Colman; the largest white Duke of Buccleuch, both of which produce berries as "large as Plums."

GAS IN CONSERVATORY—ZINC FOR VASES (A Subscriber).—If much gas is burnt in a conservatory it is injurious, and would cause the Camellias to cast their buds. Plants grow well in zinc receptacles, which are often employed for fitting into stone and other vases.

ANGRECUM SESQUIPEDALE NOT EXPANDING (R.).—The condition of the flowers we attribute to the dense fogs that have prevailed in your district in conjunction with the prolonged low temperature. Had you placed the thermometer close to the flower spike near the glass you would have found it several degrees lower than in the body of the house; but the fogs are the

principal cause of the injury, especially as you are situated near large chemical works, the deleterious gases from which could not escape from the moisture-laden atmosphere.

SAWDURT FOR MUSHROOM BEDS (E. P.).—It is not advisable to use sawdust in Mushroom beds, for although it will not kill the Mushroom spawn, it usually induces the growth of masses of other fungi, which impair the value of the bed, and sometimes injure the Mushrooms.

Value of the bed, and sometimes injure the authoroms.

ROSES IN CLAY SOIL (An Urbridge Amateur).—You may expect Roses to grow well even if the soil contains traces of iron. Some of the finest coloured blooms we have ever seen were grown in soil impregnated with iron. You can only ascertain the quantity of iron in the land by submitting a portion of the soil to an analytical chemist for examination. Plant a few Roses well, placing a little lighter compost round their roots, and we think they will grow satisfactorily.

think they will grow satisfactorily.

HEATING CUCUMBER HOUSE AND INCUBATOR (Light Brahma).—The plan you propose would answer so far as regards the circulation of the water, but we do not advise you to carry it out. If you wish to grow Cucumbers, and not red spider, you must not think of having the pipes constantly heated to 200° whether the sun shines or not; indeed during much more than half the period of growth you would not require half that amount of heat from the pipes. Either an open chamber with slates over or covering the pipes with brick rubbish will answer. A chamber would be best in your case, having sliding shutters in the wall next the path for admitting heat as required into the house. As your pipes are shown you would, were they enclosed, have too much bottom and not sufficient top heat. The depth of soil you name, 15 to 18 inches, is ample, with frequent top-dressings. The compost you name is good, surfacing the bed with manure and fresh loan as the roots protrude through the soil. Obtain water for the incubator from another source.

WHITE FLY INFESTING TOMATORS (Norice).—It is a kind of midge, and

from another source.

WHITE FLY INVESTING TOMATOES (Novice).—It is a kind of midge, and is not by any means common, and mostly infests such plants as have hairy leaves, such as Gesneras, Lantanas, &c. It deposits its eggs on the under sides of the foliage, and undoubtedly feeds on the judices of the plants. The glutinous substance on the plants is a consequence of the presence of the insects. They may be destroyed by fumigation with tobacco smoke, but upon the least presence of smoke they fall to the floor, as the smoke is not nearly so dense at the floor as in the upper part of the house. Prior to fumigating, the floor, borders, &c., should be well syringed but not the plants, and as the insects cannot endure a wet surface they will be destroyed. A few fumigations at intervals of a few days will soon destroy the pests.

CHILIAN BRET (J. M).—The chief value of this Bect is for decorative purposes, it being very useful as an ornament for conservatories, halls, &c., at this season, being taken up and potted before frost. We are not aware that any part of the plant is sellible, though the leaves would probably be available for the same purpose as Spinaoh.

PLUM AND PEARS FOR SOUTH-WEST ASPECT (II. E. B.).—Kirke's Plum is one of the finest, being large, deep purple in celour; or if you require a yellow one, Jefferson coming in early in September is excellent. Coe's Golden Drop coming at the end of September is unrivalled. Pears: Doyenne du Comice, Marie Louise, and Glou Morceau. If you require an early one Deurré de l'Assomption.

Plants for Damp Borders (Idem).—Acorus gramineus, Aronicum glaciale, Caltha palustris tiore-pleno, Cardamine pratensis flore-pleno, Dodecatheon Moadia, Epilobium angustifolium album, E. latifolium, Epimedium grandiflorum, E. pinnalum elegans, Ficaria ranunculoides flore-pleno, Bedysarum obscurum, Hepatica angulosa, H. triloba vais., Iris germanica vars. Lobelia fulgens, L. hybrida vars., L. syphilitica and var. alba, Lychnis chalcedonica and var. alba and plena, L. diurna flore-pleno, Lyshmedia grandiflora, L. thyrsiflora, Mecouopsis cambrica, Mertensia paniculata, Myosotis disstiflora, M. palustris, Nierembergia rivularis, Ophiopegon spicatus, Primula acaulis vars., Ranunculus amplexicaulis, Spirea Aruncu, S. filipendula plena, S. japonica, S. palmata, S. venusta, Trollius europeus, T. japonica plena, and T. napellifolius.

RATING GLASS STRUCTURES (Thomas Harsood).—We have no recollection of the report you mention, but if you can state approximately the time of its appearance it shall be searched for. We have repeatedly expressed our opinion that a nurseryman's and florist's greenhouses and hothouses are not rateable. They are mere shelters for his stock-in-trade, and are on a large scale what the copings on his walls and the frames on his hotbeds are Under certain circumstances stock-in-trade is rateable, but as a farmer is not liable to be rated for his stock-in-trade eleded for carrying on his business, so even if a nurseryman's glass houses were considered stock-in-trade they are needed for carrying on his business. Nevertheless, as opinions have for long differed upon the point, it is useless to discuss them in any journal, and we-strongly recommend nurserymen, florists, and others interested in the final decision of the dispute to subscribe and have the case decided by one of the superior Courts. The structures to which you refer are not exempt from the supervision of the Local Board. If the buildings are rated your appeal is to the Quarter Sessions.

FLOWER FARMING IN TEXAS (N. Hammond, Rochester, N. Y.). - You will find all the information you require in a work by Dr. Septimus Piesse, of the firm of Piesse & Lubin, of Bond Street, London.

CUTTING A DRAIN (C. J. P.).—The cost depends entirely on the rate of wages in your district and the nature of the soil. We do not give estimate of cost for executing any kind of work, and in your case no one could give an estimate without personal inspection of the site to be drained.

SNAILS IN CUCUMBER HOUSE (Snail).—The specimens you have sent shall be examined; in the meantime you must work assiduously in entrapping the posts. Perhaps a light sprinkling of greatly diluted parafin, not more than a fluid ounce of the oil to a gallon of water, might check the pests and not injure the plants; but proceed cautiously, and try it on a small portion of the bed first, and note the results.

NAMES OF FRUITS (Comber).—1, Chaumontel; 2, Dunmore. (W.S.W.).—1, Duchesse d'Angoulème; 2, Winter Majetin; 3, Barceloua Pearmain; 4, not known; 5, Scariet Crofton; 6, Adams' Pearmain. (Vomo).—White Nonpareil. (Pomo).—4, Hacon's Incomparable; 5, Figue de Naples; 8, Beurré De Jonghe; 10, Calebasse; 11, Deurre Chairgeau; 17, Nouveau Posteron.

NAMES OF PLANTS (Inquirer).—1, Libonia floribunda: 2, resembles Eranthemum sanzuinolentum, but the flowers were all withcred; 3, probably Laukesteria longiflora; 4, Chamaseyparis sphæroidea variegata.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

HOUSE AND SHED FEEDING OF SHEEP.

(Continued from page 472.)

THE first point we have to consider in accommodating sheep under cover is the construction and situation of sheds. This is really a very simple matter as regards the sheds, for on almost all occupations or home farms they will be found fit for the purpose by adding internal divisions and fittings, which will answer nearly every purpose for which they are required. For instance, we seldom find premises without some kind of shed, and which is often used for comparatively unimportant purposes, but which may be made useful for feeding sheep under cover with very little if any alteration except that of division and the arrangement of the floors. With regard to the erection of a new shed this need not be of an expensive character, for a lean-to shed attached to almost any building can generally be made suitable to our purpose if the aspect is south or south-west. Let us take first the adaptation of an ordinary shed. The first thing necessary is to appropriate the floor under cover without reference to any outside convenience. The shed should be wide enough to afford a feeding path at the back or under the higher side of the roof, and sufficient for a man with a barrow to pass along. The divisions of the pens may be made with wattled hurdles or iron hurdles, the latter being best and most durable, and will show the stock to better advantage; and whether we require to pan ten or twenty sheep, it is easy to plant either of these temporary fences at a sufficient distance apart, supposing the shed to be 10 or 12 feet under cover besides the width of feeding path, because a space outside may be used or not as required. For instance, if there is an abundance of straw to be converted into manure a space outside may be allotted to each, 10 feet under cover according to circumstances, as 10 feet by 12 feet under cover will afford ample protection and lying for eight or nine animals of the down breed according to fatness, but for the larger and long-woolled sheep only seven or eight animals.

Having arranged the pens for feeding and for littering with straw it must be understood that the pens, both inside and outside, must be covered at the bottom with dried peat, clay, ashes, or ordinary soil. The inside of the pens should be raised by mould put in dry quite a foot higher than the outside of the pens, the inside being laid with earth 18 inches deep, and the outside about 6 inches. The pens should be littered with dry and rather short straw or haulm as cleanliness dictates, the manure being allowed to accumulate under the animals. have, however, to provide against the heating of the dung, but to prevent this fine dry earth, ashes, or peat should be strewed over the pens every other day in moderate quantities; this application will not only prevent the mass from fermenting and heating, but will fix the ammonia and prevent any evaporation of the most volatile portions of the manure. By these means, together with the firmness and solidity of the manure, will prevent the animals from suffering from lameness or foot rot. We must, however, leave it to the discretion of the home farmer, and the objects which he may have in view, as to whether he will put his sheep entirely under cover or only partly so, for we advise that fatting sheep should be entirely under roof. Store sheep brought to the shed for convenience in the case of bad weather for a time, or for the consumption of roots in preference to feeding them in the field upon strong heavy land in the winter months, may have a space outside as well as inside. observations, however, apply chiefly to occupations where plenty of straw is available, but where it is scarce and dear the floors of the sheds may be excavated about 18 inches in depth, and earth, &c., filled into the pit, but the materials may be the same as before stated of a certain depth; there should then be a framework about 1 foot above it supported by blocks of wood, the framework being in squares of 5 feet by 6 feet to facilitate

removal; the frames should be of oak, the spanes or spars being 2 inches by 24 inches, and placed with a three-quarter-inch space between them; the liquid manure will then pass through freely. But the pens must be swept twice daily with a birch or base broom, the excrement will then pass through also into the pit below, but the sparred floor should be daily dusted over with a small quantity of dry sifted or screened earth mixed with pow-dered gypsum. This application will effectually remove any unpleasant odour, and at the same time assist in fixing the ammonia. By following these plans of shed apartments the home farmer will not only obtain the full value in mutton for the food consumed by the sheep, but will at the same time secure the largest amount of valuable manure in proportion to the food consumed. It must, however, be quite understood that attention will have to be paid to the absorbent materials, because when they are fully saturated they should be removed. They will be found in practice extremely valuable, and when placed in a dry They will be manure house will be ready at short notice to be converted into a state fit for drilling with the various farm crops, but especially state fit for drilling with the various farm crops, but especially will they be valuable as an application for mangolds, carrots, cabbages, &c., and other crops requiring ammoniacal manures. We will now refer to the method we advise in erecting a new building for the purposes of house feeding; and in doing so we think that it would be well to make the pits and pens so that they may not only accommodate either bullocks or sheep, but be account to the property of the pension of the pension to constructed as to be used as hoves for the menure to account so constructed as to be used as boxes for the manure to accumulate under the animals with straw bedding, or be used as pits partly filled with earthy materials, the animals standing on sparred floors, and the manure saved without any litter, as above alluded to.

Having many years ago paid a visit of inspection to some of the most noted establishments where the house feeding of sheep was being carried out, we found the three most important and peculiar being carried out, we found the three most important and peculiar were those of Sir Richard Simeon at Swainston in the Isle of Wight; the Rev. Anthony Huxtable at Sutton Waldron in Dorsetshire; and J. J. Mechi, Esq., of Tiptree Heath in Essex. We found it really very interesting to see the system of sheep-feeding under cover adopted at Swainston by the late Sir E. Simeon, and in describing it we may say it was stall feeding in miniature compared with stall feeding of bullocks, the sheep being external to the finding management of the statement in a described in the statement in tethered to the feeding manger about 2 feet apart in a double row with feeding path between; the essential difference, however, being that instead of the liquid manure being allowed to drain away from the stalls by a gutter as for bullocks, it was at Swainston so arranged that the hinder part of the sheep stood upon grating with a pit beneath about 2½ feet wide and 2 feet deep, so that both liquid and solid manure passed into the pit to be removed daily, the urine flowing towards a tank for the preservation of the manure, to be afterwards prepared for use by admix-ture with earth or ashes. We have been informed, however, that the sheep would not be uniformly healthy unless the manure was removed daily. Mr. Huxtable's system of feeding on boarded floor, whereby the manure passed through into pits beneath, was designed to save the manure in a semi-liquid state, and, passed on daily from the pits into a large tank or reservoir, was treated as before stated, being mixed with ashes, &c., for use in drilling for the production of farm crops. It has, however, been stated that the animals often suffered in health, and no doubt from the effluvia resulting from the manure under the grating not being entirely cleared away. In consequence of this Mr. Huxtable reverted to the plan of stalling originally invented or adopted by Sir R. Simeon, and this he continued for some years with satisfactory results as long as the pits were daily cleared out and the contents passed to the tanks. Mr. Mechi's system was similar to Mr. Huxtable's first plan, pens with sparred floors through which the manure passed into the pits beneath and flushed with water to pass it on towards the tanks, where it was collected to be distributed by pump and hose over the farm crops in a liquid state instead of being treated with earth or ashes for drilling.

(To be continued.)

WORK ON THE HOME FARM.

Horse Libour.—Although there is much land in various districts intended for wheat still unsown, the frost has lately been so severe that nothing of any consequence has been done in sowing since the 25th of November. There is, however, much valuable work going on upon certain farms, particularly in those cases where the wheat stubbles were cleared of couch and weeds in October, for we have seen the dung being laid out lately, and in consequence of the hard frost it is done without injury by horses and carts. The preparation for mangolds with manure carted on and spread upon the land will, as soon as the frost breaks up, be ploughed under, leaving the land in capital tilth for sowing the mangold seed at the earliest time, for we believe that April is the best month for drilling or dibbling the seed especially upon the cold land in late and backward climates. As far as our experience goes, we have never succeeded better in obtaining a heavy crop than by dibbling on the balk or stetch. It is not, however, in every season that the land will work kindly and fine enough for dibbling mangold seed, but there is a fair prospect that it may prove so the next

or coming year. We are much grieved to see the general state of the land intended for root crops next year, for in almost every instance where the home farmer did not employ steam power to autumn-cultivate, the fields are in a bad state with couch and weeds owing to the wet season. The acreage of land both for wheat and roots is large where the land could not be got into condition, and is still left unsown, the root land to come in for barley, and land set out for wheat will in many cases also be put in with barley, for it is only after favourable weather in the spring that it can be cleaned in readiness for the seed time for Lent grain of any kind. During the late frosty weather much chalk has been laid out, and will soon be reduced by the frost into a nice state for mixing with the soil when required. There has also been much dung laid out on the clover seeds, and it is a good plan not to let the dung accumulate in the yards, for the fresher it is laid out the better, especially from the cattle boxes; besides which, when dung is laid out on the young seeds it protects them during frost and improves the land on the return of mild and growing weather. It is best, however, that the dung should be spread as fast as it is laid out.

Hand Labour.—The water meadows should be constantly attended to, for although during frost the grass will often be covered with ice this must not prevent the regular flooding of the meadows; for not only does the land under the ice maintain a higher temperature than any part not flooded, but it is always ready to receive the first flood when the thaw sets in, and which is the most valuable, because it brings down from the hills earthy deposits so valuable in irrigation. The herdsman and dairyman even during frosty weather, if no snow is on the ground, should allow the young cattle and the dairy cows to run upon the pastures for a few hours in the daytime, especially on pastures that have not been fed close or the tufts not cut down during the autumn, because the grass which has not been closely fed or rejected by the animals will often during a frost prove useful grazing; at the same time it is healthy for them, and preferable to straw or inferior hay given in the yards or sheds. Sheep, however, but especially the hungry breeding ewes, should not be allowed to graze the pastures during winter's frost, because they bite so closely that they often kill the best and sweetest herbage plants, and should therefore be taken to feed in the wheat stubbles and the old clover leas which are to be ploughed up in the spring. The sheep also do very much injury if they feed on the young clover plants or saintfoin; the latter is often seriously damaged by winter feeding. The fatting sheep will now be on root-feeding, but the ewes in-lamb, although they go out to graze during the day, should at night be penned in a dead fold placed in a sheltered position. This applies more particularly to the Dorset Downs, and those which begin lambing early, and so that the lambs may be fat and ready for market at Easter. The feeding of both cattle, sheep, and horses is now a matter of more than usual importance, owing to the short root crop and injured hay crop; we therefore recommend the home farmer to study the position in which he is plac

STRAINS OF POULTRY.

WE promised to give some hints on the judicious mating of poultry for breeding; but, as so much of our intended advice is connected with the question of strains, we will first briefly refer to that subject. The intending purchaser of poultry generally thinks it necessary to inquire from whose strain the birds were obtained. The question is often put by the initiated with a definite purpose—viz., to avoid mixing up different strains; but more often it is asked from a vague idea that for success in poultry breeding there is nothing like crossing as many strains as possible. As a rule, the answers given to such queries, save by really careful breeders, are very misleading and unsatisfactory, from the real ignorance of most poultry keepers of the antecedents of their stock. The vendor has perhaps had eggs from a yard, some of the birds of which came in the egg from the celebrated yards of Mr. So-and-so. They are therefore called of his strain, though possibly the eggs which originally went out of the famous yard were laid by birds which had only just come into it! We are not, however, dealing with the chances of that part of the question, but are presupposing that the eggs or birds really

come from their reputed strain. It is a well-known fact that fresh blood must at times be introduced to keep up the vigour of any race. This principle has been exaggerated into the belief that constant "changes," as people call them, are necessary. No greater mistake can be made; the idea must be entirely discarded by anyone who wishes to breed scientifically—that is, who wishes to acquire and keep up a breed with certain definite characteristics of form and feather. It is, we believe, a fact that almost every fancier who has established what may fairly be called a strain of his own has obtained it either by originally purchasing a considerable number of birds from one good yard and breeding judiciously from them, or by selecting particular families from among his own birds, in which he has observed certain excellences to be hereditary, and mating related birds from these families together up to a certain point. The former course is probably the shortest route to fame, but the "goodwill" and stock of a famous yard are seldom bought for little. The latter takes time; but it is the method most suitable to the taste of a true fancier, and ever full of interest, to watch the gradual development of peculiar beauties in individual birds, and to trace them among their descendants. We have done it with several breeds, and to us half the charm of watching the daily growth of the young stock rests in observing their strange likenesses to ancestors of the third and fourth generation back—often some famous winner, perhaps the very father or mother of the race, seems veritably to live again in a descendant. As we see old family portraits looking down upon succeeding generations the very image of themselves, so, too, in birds have we seem marvellous resemblances—combs, feet, movements exactly like those of some favourits of past years. The possession of a strain which year after year may be relied upon almost unerringly to produce stock of the highest merit and of one particular type is indeed something to be proud of; it is

CANTERBURY POULTRY SHOW.

The seventh annual Show took place at Canterbury in the large Pavilion. It was this year confined to the six home counties, but the poultry classes were quite equal to those of previous years in quality when this has been an open Show. There were 910 pens altogether, and doubtless would have been more if the Ryde Poultry Show had not been held at the same time. The arrangements were good, as they always are at Canterbury. The Judges of poultry were Mr. Teebay and Mr. J. Nichols; Pigeons, Mr. Tegetmeier; Rabbits, Mr. Jennings; Mr. Billet presiding at the pens as usual. Catalogues with awards were printed, and in the hall at four o'clock on the opening day.

The Dorkings, as usual in Kent, were largely represented in fifty pens of more than average merit. Cochins. for a local Show, were good, Mrs. Christy in her cup pen having a hen of rare excellence. Light Brahmas were more numerous than the Dark; the cup was awarded to the latter, as it generally is when these classes

The Dorkings, as usual in Kent, were largely represented in fifty pens of more than average merit. Cochins, for a local Show, were good, Mrs. Christy in her cup pen having a hen of rare excellence. Light Brahmas were more numerous than the Dark; the cup was awarded to the latter, as it generally is when these classes compete together. Game had forty-eight pens, and Selling classes contained a few good birds and cheap. Pigeons were not so numerous, and equal in quality to those of last year. Rabbits were largely represented by the leading fanciers. I enclose a prize list, and hope you will print the awards, as they speak for themselves.—An Old Exhibitor.

[No prize list came to hand.—EDS.]

THE BEST VARIETY OF FOWL—LANGSHANS.

SEEING in the last number of the Journal of Horticulture an article headed "What is the best variety of fowl?" I cannot refrain from saying a few words on the subject. For the last twenty years I have kept many kinds of fowls at various times, but always high-class birds. I do not exhibit, but for the last four years I have been fortunate in possessing Langsham, for I say unhesitatingly that both for laying and eating purposes they are the finest fowls I have ever met with. As to their likeness to Cochins, they resemble them only in the one good quality those large coarse birds possess, and that is they do not wander about. Their flesh is perfectly white and delicate like the Dorking, and not yellow and coarse like the Cochin. They are splendid layers, and are less broody than most fowls. The prejudice against them by exhibitors is quite a mystery, and the desire to mix and confound them with Cochins is, to my mind, inexplicable. Many friends who have seen my birds and tasted them have given up both Cochins and Brahmus in their favour with most satisfactory results, and I think it is well that the public generally should be made aware of the value of the birds.

In addition to their being good layers and splendid table birds, the chickens are hardy and quick growers, and therefore soon ready for use. During last spring we hatched and reared sixty-three birds, and never lost one, although my neighbours suffered heavy losses among their Dorkings and Brahma-Dorkings from gapes. The young chickens are fed on barley and scraps; the gapes. The young chickens are fed on barley and scraps; the older birds on Indian corn morning and night, and scraps mid-day. As I neither show nor sell my only object in sending you these few lines is to let the public generally know the value of the genuine Langshan fowl as a bird quite distinct from the Cochin breed. I presume the love of exhibitors for Cochins and Brahmas is on account of the enormous size those birds frequently attain.

—JOHN CLIMENSON, Shiplake Vicarage.

NEW BOOK.

The Practical Pigeon-keeper. By LEWIS WRIGHT. Cassell, Petter, & Galpin.

This is a companion volume to "The Practical Poultry-keeper," by the same author, that was published twelve years ago. Being crown 8vo. it is just the size for the hand, and just the right size as to contents, being large enough to give much information,

while it is not bulky, gorgeous, and expensive.

while it is not dulky, gorgeous, and expensive.

In one marked respect "The Practical Pigeon-keeper" is a great improvement upon "The Poultry-keeper," for the illustrations are vastly superior. They are by Mr. Ludlow, who knows well how to draw a fancy Pigeon. As regards the letterpress the weil now to draw a rancy rigeon. As regards the letterpress the author has, from long practice, become a skilled writer, exactly, and often very happily, conveying to the reader what he means; he also proves himself to be a good and capable fancier. It would have been convenient for the learner had a few introductory lines been given relative to the older writers on Pigeons, with the dates of their works; this, I venture to hope, will be done in future or their works; this, I venture to hope, will be done in future editions. I am glad to see that the good old plan has been followed of taking the standard English varieties first, and particularly that very little is said about German Toys, which some writers weary us with—birds which never have been cared for in England. I am glad also to see full accounts of the frilled Pigeons, for their singular beauty of outline, colour, and softness of feathers are so very attractive.

But I am anticipating the cardy of the book. Eight a charter of the

But I am anticipating the order of the book. First a chapter on the Pigeon loft and its arrangements, with excellent plans; then the second chapter gives an account of the best food and ways of the second chapter gives an account of the best rood and ways of feeding; Chap, iii. breeding and general management. I notice that under this head advice is given "to turn one pair or two in by themselves, and they will soon choose a home." I have always found it a better plan to fasten each pair when mated into a pen, placing a wire slide or cage in front of it, and then they will make this their home, and no other birds will disturb them. Chap, iv. placing a wire slide or cage in front of it, and then they will make this their home, and no other birds will disturb them. Chap. iv. is on pedigree breeding. This is both interesting and useful. Next comes the inevitable chapter on exhibiting Pigeons. When we come to varieties we have, most properly, the Carrier placed first. One little criticism I would make. It is stated on page 75, that "In Moore's day the eye wattle had attained the size of a shilling or nine-tenths of an inch." Exactly so, in regard to the size of a shilling of Queen Victoria's reign; but Moore lived in the reign of George II., and a shilling then, and I have one that appears never to have been in circulation, was a full inch in diameter, which makes some difference so that Moore's Carrier was a good bird in makes some difference, so that Moore's Carrier was a good bird in eye wattle. Dragoons, as kin to Carriers, naturally come next; but our author actually places Barbs before Short-faced Tumblers! I am afraid that could the Barbs read they would become awfully conceited. To my thinking Tumblers should have come next, and then Pouters, for Barbs have only just been admitted into the aristocracy of Pigeons. In the chapter upon the Almond Tumbler I am pleased to see the plan advocated of placing feather before head and beak. This is going back to the good old lines, and discouraging cruelty. We want beauty of plumage to be first considered, and a blow given to those who make the short face by cruel pressure, actually killing many birds by the use of their skull-crushing machines. The chapter on Pouters, like those on the Carrier and Tumbler, is an able one. The Fantail and Jacobin are next fully treated of. The illustrations, ten in number, of these feathered gems are very excellent, particularly of the Turbiteen and Blue Vizor. May we all see more of these lovely birds, which are described as "the most fascinating in appearance of all the Pigeon tribe." Remarks on the exhibition Antwerp. with many diagrams, follow, forming Chap. xv.; while Trumpeters, Archangels, Nuns, Magpies, and Runts are compressed into Chap. xvi. A chapter on Eastern Toys, another on various German Toys succeed, when a treatise on those birds of utility, Homing Pigeons, naturally follows, and concludes the varieties. Some handy notes on diseases of Pigeons finish the volume. cruel pressure, actually killing many birds by the use of their

volume.

The "Practical Pigeon-keeper" is an able book, and to an unusual degree in these days an original book. The author shows that he will not be tied down to old mere fancy notions, but keeps in view true beauty. As an instance I quote what he says in regard to the Carrier—"The neck should be as thin as possible at both extremities—that is, thinning almost suddenly at the

shoulders and running up to a fine clear-cut gullet; and a bird with these properties and their relatives—that is, with a long than neck, long limbs, and long tight feathers, is said to be fine and racy-locking. It may be added that these latter properties have most of all to do with the real sesthetic beauty of the Carrier, and that they are rarely found in old birds. The great weight of the adult wattle puts too great a strain on the muscles of the neck, so that it becomes coarse; and here again we have a strong reason for insisting that certain points should not be developed in mere size any further than is consistent with other properties." I think we want more of this aiming at real and proportionate beauty in Pigeons. There is a true beauty in everything, which should be sought for, but Pigeon fancying has been too much the magnifying of deformities .- WILTSHIRE RECTOR.

VARIETIES.

WE are sorry to hear that the whole of the beautiful stock of Dark Brahmas belonging to the Rev. Hans F. Hamilton is in of Dark Brahmas belonging to the new Hans r. Hamilton is in the market. It is little more than a year since in "Famous Poultry-yards" we expatiated on the merits of his stock, which has been collected at immense cost. We are glad, however, to learn that Mr. Hamilton is not entirely retiring from the fancy, but wishes to devote all his space to Dorkings.

· WE have the schedule of the Swindon Show of Poultry and Pigeons, to be held on the last day of this year and the first of the next. The classification is very good, but the first prizes are only 10s.

— THE Surrey Columbarian Society will hold a Show in the Skating Rink, Guildford, on January 6th and 7th.

THE list of prizes offered by the Bath and West of England THE list of prizes offered by the Bath and west of England Society and Southern Counties Association at their meeting at Worcester next year has just been issued. The main features are similar to those of the Exeter list, though with the addition of some specially local classes by the Worcestershire Agricultural Society. The principal alterations in the live stock regulations are occasioned by the change in the day of opening the Show. For the first time the Exhibition next year will open on a Wednesday (June 20th). Stock will be day (June 2nd), and close on a Monday (June 7th). Stock will be received into the yard on Monday and Tuesday, the 31st of May and 1st of June, and probably in the case of most exhibitors the and 1st of June, and probably in the case or most explosions the change will be acceptable, necessitating a shorter absence from home than under the old arrangements. The prizes for poultry are of the same amount as at Exeter, though considerable alterations have been made in the arrangement of the classes; and by doing away with one or two which were considered unnecessary, additions have been made for the encouragement of new and popular breeds.

THE long-continued frost with snow has completely stopped wheat-sowing in Essex, and many farmers on heavy land have little or none sown at present. Many acres of mangolds unfortunately not secured are completely spoilt, and as a consequence prices will inevitably be high.

—— THE Doncaster Agricultural Society's next exhibition has been fixed to take place on Wednesday, Thursday, and Friday, June 28rd, 24th, and 25th, 1880. Entries close on May 29th.

MR. LAURENCE PEEL, Clerk to the Privy Council, has, referring to the restrictions placed on the importation of foreign cattle, remarked on the singular fact that, in spite of more stringent rules, the number of cattle brought into England during the first ten months of the present year was nearly fifty thousand in excess of the number in the corresponding period of last year. As regarded foreign competition in meat farmers should bear in mind that the cost of freightage was one of the most important items in this trade, and that whereas freights were exceedingly low, now with improved trade generally this expense would be nearly doubled. They must add to this the danger of the sea passage, for although this item had been small in proportion this year no less than twelve thousand animals were thrown overboard or lost by death and exhaustion in 1878.

— At the annual meeting of the Boyal Agricultural Society held last week it was stated that the Society now consists of 82 life governors, 71 annual governors, 2619 life members, 5099 annual members, 20 honorary members, making a total of 7891, and showing an increase of 1094 members during the current year. The Council had the pleasure of announcing that the Prince of Wales having a verses of a design of taking part in the preceding of the proceedings. Wales having expressed a desire of taking part in the proceedings of the Society as a member of the Council, His Royal Highness had been unanimously elected a Trustee of the Society. By the end of this year the funded capital of the Society would have been reduced by the sum of £14,000, of which nearly £12,000 had been required to meet the deficit in the receipts at the Kilburn Exhibition, while the balance had been devoted to the building of the new laboratory and to the purchase of plant and materials for the Carlisle meeting next year. The funded property of the Society at the end of the year would stand at £12,511 11s. 5d. New Three per Cents., and the balance of the current account in the hands of the bankers on the 1st inst. was £1895 19s. 6d., which, however, was not sufficient to meet the outstanding claims connected with the London meeting. The magnitude of the Implement Show at Kilburn had again drawn the attention of the Council of the desirability of curtailing this department of the Society's country meetings. They had resolved that the maximum size of stands be 150 feet. The Carlisle meeting will commence on Monday, July 12th, and close on Friday, July 16th.

MODERN BEE MANAGEMENT .-- No. 14. FOUL BROOD.

THE subject of foul brood having lately occupied considerable attention in the columns of our Journal, I venture to submit the results of my experience with it, as being at present more seasonable than the subject I had intended to introduce at this point in my series. Like some others I at one time strongly suspected that the pest was in some way connected with the importation of Ligurians, but a wider experience convinces me that such suspicions are unfounded. It is doubtless true that those who have advanced so far as to introduce foreign blood into their apiaries advanced so far as to introduce foreign blood into their apiaries have generally been the first to detect the existence of foul brood. But there is no just cause in this for connecting the two. The very skill and experience of such bee-keepers makes them the likely persons to make the discovery, and as a matter of fact I have found foul brood most rampant in remote localities where Ligurians had never been seen. I could instance half a dozen of such localities in Scotland. In one district in particular, at the time I was about to introduce Ligurians there for the first time, I discovered to the alarmed bee-keepers that nearly every stock over a wide district was badly affected. They at once understood the reason why, in spite of splendid natural advantages, they had for years had such a struggle to keep stocks in good condition. the reason war, in spite or spiendid natural advantages, they had for years had such a struggle to keep stocks in good condition, and why their per-centage of losses was so extremely high. Infected stocks were dying out at all seasons, the combs being either laid out as food (?) for the remaining stocks, or preserved for placing swarms in. No wonder the disease took such a hold on the district, that even after three years of earnest effort it is still a rare thing to find a stock clean. Facts like these are to my mind conclusive as to the immediate origin of the pest. It is indigenous to the country.

The nature of the plague and its symptoms and methods of propagation have been so well described by others that I need propagation have been so well described by others that I need not further refer to them here. I shall only refer to my own experience with it. In 1876 I first observed it in a stock which I had remarked as having commenced brood-rearing long before any of the others—in fact, it had a large card of brood on New Year's day. Early in the spring the disease had developed to such an extent that the smell was very observable in the neighbourhood. I at once took the severest measures for its suppression. No application of salignific acid had the least effect to sion. No application of salicylic acid had the least effect, so I reluctantly destroyed the whole of the combs. I saved the bees, and by carefully disinfecting everything in the neighbourhood by the use of carbolic acid I had the satisfaction of finding no

In the spring of 1877 I discovered a fresh outbreak in a stock that had yielded over 100 tbs. of super honey the previous season. In this case I had no doubt of its origin, as I remembered that this particular stock had robbed out a distant skep in the autumn previous. Here again I used salicylic acid solution so strong that most of the adult bees were killed by it, but with no effect. Three weeks after the syringing of the combs the appearances of the brood gave evidence that 90 per cent, was diseased. Total destruc-tion rid me of the plague for a second time. The results of these experiments convinced me that it was hopeless to attempt a cure so long as any foul cells remained in the hive; I therefore resolved that if I should be so unfortunate as to have further experience of the malady I should at once transfer the bees to clean combs. Last spring I found traces of foul brood in two bar-frame stocks I had purchased; these I put on clean combs and fed the bees with medicated syrup. In one I found nine cells of the first hatch of brood again diseased. These I at once cut out, and thereafter that stock prospered. The other stock never had another trace of disease. Doubtless the nine cells referred to had been infected by the food carried in the stomachs of transferred bees, and as they were cut out before they had reached the contagious stage there was no further outbreak. A neighbouring bee-keeper had quite a number of stocks infected last spring; they treated in the above way and came out clean. I may add that the salicylic acid used was dissolved in alcohol. I am not so certain as to the result when it is dissolved in borax and water. Experiments ought to be made with both solutions on various fungoid growths before we can be certain that the compounding of the borax and acid does not diminish the antiseptic power of either. I mean to have this tried soon, and also the remedial powers of a I mean to have this tried soon, and also the remema powers of a recently discovered vegetable antiseptic said to be even more deadly to fungoid growths than salicylic acid itself. This substance, thymol, being an extract of wild thyme, may perhaps prove Nature's own remedy to the worst disease our honey gatherers have.

The results of my experience lead me to warn bee-keepers every-

where against tampering with foul brood. The sternest measures must be resorted to. Spring is approaching when, from the general absence of brood, it is the safest time to transfer infected general absence of brood, it is the safest time to transfer infected stocks. Let this be done in every case where the disease has manifested itself to any serious extent. Where only a few foul cells are found, and in all hives whatever, the medicated syrup should be used after cutting out the bad cells. In order to reach your neighbours' bees as well as your own set up a public drinking fountain well supplied with strongly-dosed syrup. At my suggestion this has been done in several infected localities, and I have no doubt will result in at least a mitigation of the foul plague.—WILLIAM BAITT.

OUR LETTER BOX.

FOWLS LOSING FEATHERS (J. S.).—The cause may be as you suggest, and you cannot err by affording them plenty of dry sakes or soil to bask in. Baldness of the liead and neck is also caused by a defect of wholesome and green food; the remedy then is good feeding and plenty of green food, at the same time rubbing the bald place with murcurial outtment, and giving a 5-grain Plummer's pill every second day for a week. Soft food is meal that has been scaleded or mixed with water, and formed into a rather dry past. The barley to which you refer will do the birds good and not harm. FOWLS' HEADS SWOLLEN (A. B. C.).—Your birds are suffering from roup, which is caused by exposure to excessive wet and cold. Wash the heads of the birds once or twice a day with tepid water, and give sulphate of copper, one grain daily to each bird, mixed in extensal mashed with ale, and plenty of green food. As the disease is contagious separate the affected fowls from the others.

LIME FOR LAND (Norice).—Lime burnt from limestone will be equally efficacious for your purpose as lime burnt from chalk.

FOWLS UNHEALTHY (Inquirer).—Your fowls are suffering from the effects of the extremely cold weather. Keep them under cover for a few days and give them nourishing food—barley or oatmeal mashed with ale, with kitchen scraps including small bits of meat, as they have not been able to pick up insects for some time. Green food is also essential, with whole grain at night.

HIVES (L. L. K.).—We hope very shortly to be able to give the particulars you require.

REMARKS.

-Dull in forenoon, fine afterwards; clear frosty evening.

-Dark, foggy, frosty morning, little sunshine in middle of day, but hazy throughout; cloudy evening.

-Poggy morning, damp day, partial thaw, bright sunshine at intervals; thaw continued during evening, although the sky was nearly cloudlers. cloudless

cloudless.

18th.—Extreme darkness came on at 9 A.M., greater than on any occasion that has occurred for upwards of twenty years. In a room with large window facing S.W. it was impossible to see white paper lying on a black table. It continued equally dark until 10.35 A.M., when the outlines of some poplars 200 feet distant just became perceptible, although the white paper could not be seen at 11.20 A.M., the outline of the piece of paper was just traceable; at noon decidedly lighter, but the difference between plain and printed paper only just perceptible; dull and overcast rest of the day.

14th.—Overcast throughout the day, damp, calm, and dull; snow all gone. 15th.—Dull, calm, very damp day; fog at night.

16th.—Dull hazy day, just a glimpse of sunshine about noon; foggy afterwards, and frost more severe towards night.

A very unpleasant week, much fog, and continuously cold damp air. Barometer very high.—G. J. SYMONS.

COVENT GARDEN MARKET .- DECEMBER 17.

THE supply of vegetables has been somewhat better during the week and prices easier, but trade generally is quiet and shows few signs of the approaching season. PRUIT.

ROSES AT CHRISTMAS.

HAT season of the year reminds us more of festivities than the present, when all hearts should be glad? and what amongst the beaushould be glad? and what amongst the beautiful can give more pleasure and delight than the expanding Rose bud? We know the popularity of all fragrant flowers, such as Mignonette, Violets, Carnations, &c., through the dark days of winter, yet we have found solitary instances where fragrant flowers are not in demand. The Rose is more admired than any known flower, and great attention is bestowed upon it to produce bleoms of fine size, colour, and symmetrical outline worthy of the great summer exhibitions. Writers have not failed in laying down rules how to grow and show Roses in the best condition, but modes of obtaining them at Christmas have not been sufficiently detailed; yet their value at this time is so great that the best means of producing them should be afforded, and the subject should have the attention of all practical cultivators.

Any attempt to produce blooms of exhibition quality at this season of the year would be vain. The Hybrid Perpetuals are not suitable for affording flowers in winter. For this purpose we must depend upon the Teas, which are most accommodating, and they may be had in bloom at almost any season of the year. The varieties are by no means numerous that will endure winter forcing and develope their flowers when darkness and fogs predominate. We may press the importance of losing no time in preparing the plants if growers intend in a future year to have Roses at this date. The preparation of plants for winter forcing cannot be accomplished in less time than is needed to prepare plants outside for yielding exhibition blooms during summer, and flowers cannot be obtained six months before their usual time without forethought and careful attention. To establish the plants for winter flowering they must be induced to make an early growth, the wood being thoroughly matured, to be again succeeded by a still earlier growth another year, until their nature appears changed or they start into growth with but little forcing in October. When the plants are in that state there is little difficulty in having Roses at Christmas.

Even amateurs with perhaps only moderate accommodation may be in possession of a few Rose buds during the closing days of the year if the rules we intend to lay down are carried into effect and intelligently observed. Roses can be produced at this date in pots or planted out. The former for the amateur might be found more accommodating than the latter; but the greatest return for the labour expended will be from those planted out. In forcing the Rose strong heat must be avoided; the temperature should never exceed 55° by night on mild occasions during winter, and in sharp Weather 50° is sufficient. We have more than once wondered Where Roses are in great demand that a house is not de-Voted to their culture and the Roses planted out. A span-Poofed structure is the best, extending north and south, so that the greatest amount of sunshine can fall upon the house during winter. Two rows of pipes round the house

are sufficient, with a bed in the centre in which the Roses can be planted out and trained on an arched trellis. roof must not be entirely covered, or else those beneath will be too much shaded, and but little success can then be attained. It will be well to have a small stage around the sides of the house upon which Roses in pots can also begrown. The majority of Tea Roses do well on the Manettie stock, upon which they can be grafted with the greatest-ease. The stocks can be purchased cheaply and potted in small pots, and when root-action has well commenced, and the wood intended for the scions is half ripened, the operation can be performed with success. Plants ready worked and growing freely in the spring can, however, be purchased from any well-known nurseryman, and this is, perhaps, the best course to pursue,

We will consider the plants are growing in 5-inch pots, which should be the first shift after the scions are well united to the stocks. If a slight bottom heat can be afforded the growth will be rapid, and flower buds must be removed as they appear. When the roots reach the side of the pots the plants are in good condition for turning out, providing: the borders in the house are ready and the soil has become thoroughly warmed. Before planting they should be lifted from the bottom heat for a short time. The soil for the plants in pots should consist of good loam, with one-seventh of well-decomposed manure and sand. We urge the importance of not using vegetable matter amongst the soil for the border, but substitute quarter-inch and half-inch bones mixed with wood ashes or charcoal broken small, and coarse river sand. Stimulants are best given in the form of liquid manure, and further assistance can be rendered by rich top-dressings. The plants in the 5-inch pots, if the border is not prepared, can be potted into 7 and 8-inch pots: according to their strength. Bottom heat is still serviceable, and the house in which they are to grow should be kept somewhat closer until the roots have again taken tothe new soil. It must be borne in mind in all stages of their development they must be liberally supplied with air to maintain a sturdy growth, and cold draughts on all occasions must be avoided. Those intended to be planted out should be attended to as early as possible, as underthe planting-out system they attain greater vigour and strength, and cover much more of the trellis than if kept: in pots late. From this planting time if deemed desirablethose in pots can be grown in the same house and under the same conditions as regards temperature, air, &c. The external atmosphere will by this time render artificial aid unnecessary. The house can be closed in the afternoon, allowing the temperature to rise considerably. The syringe should be employed twice daily in order to keep the foliage clean and healthy. If green fly appears in any stage fumigation must be resorted to, but we have found soft soap more satisfactory, say 2 lbs. boiled for half an hour in an old saucepan and mixed with about four gallons of water. One pint of this should be used in each large can of water at syringing time. This keeps the plants free from spider. fly, and that most troublesome of pests "mildew," and at the same time imparts to the foliage a fine glossy appearance. The remaining plants, or those in pots, can if their progress.

NO. 1630 .- YOL LXII., OLD SERIES.

No. 978.—Vol. XXXVIL, NEW SERIES.

has been sufficiently rapid be transferred into 10-inch pots, and the weaker plants can remain in their 8-inch pots; but this is a question that must be left to the judgment of the cultivator.

When autumn approaches the wood must be thoroughly hardened and ripened, and the plants brought to a complete rest by maintaining the atmosphere of the house dry and cool. Here we may safely point out the advantages of the rest we advocate. For instance, a house of Tea Roses for producing flowers in winter which came under our notice. Healthy vigorous plants were planted during summer in a border similar to what we have described. They progressed favourably during late summer and autumn, and, instead of receiving that rest so essential, they were kept slowly growing all winter because they continued to produce a few solitary buds. Their growth during spring and early summer following was weak. puny, and insignificant, almost covered with mildew. Many of the plants required that long rest we have on past occasions pointed out in the Journal, and were only fit for the rubbish heap, where the greatest portion of them went. The border with other things was considered as the cause. But the unnatural system practised in keeping them constantly growing enfeebled the plants and ruined their constitution. During our experience we took the charge of a house similarly treated, and we failed with every attempt to encourage growth. It occurred to us that the plants were exhausted. Nature was allowed for a time to take its course in early summer, when growth should have been vigorous and free. After this we again gently excited the plants into growth, which was vigorous and strong, although unripe and unfit for the production of first-rate flowers. The growth has been ripened earlier each year. Another season, and then they will be in good condition for the production of flowers at Christmas. Those young plants subject to autumn and winter maturation, should after rest be slightly pruned by removing weak and unripened shoots, and should be again slowly started into growth. It will be wise if the flowers are sacrificed and the strength of the plants devoted to the production of wood. They can be gradually started in January instead of a month later, by maintaining a temperature at first of 45°, and as growth progresses it should be raised to 55° by night, with a gradual rise by day from sun heat. The growth should be completed as early as practicable, so that earlier starting can again be resorted to until the growth is made sufficiently early to be started in October. If the Roses are in good condition and prepared as described, and started ten weeks before Christmas, the cultivator will not fail to have Rose buds at this festive season, and certainly no flowers that he can produce will be more highly appreciated than these fresh and fragrant Tea Roses.

Such varieties as Gloire de Dijon, Lamarque, Belle Lyonnaise, Maréchal Niel, and other varieties of the same habit of growth, should, if in pots, be grown on the same principle as pot Vines, with the exception of temperature. One shoot only should be allowed to grow as long as possible without pinching the end. When the plants are well established they will grow many yards in length during a season in 10 or 12-inch pots. The unripe ends at pruning time only should be removed, and the long strong shoots trained round four stakes inserted round the side of the pot. After resting they can be started, and will produce a bloom from every eye along the shoot. With a number of plants they can be subjected to early growing, and, like pot Vines, can be grown to start at any date. Gloire de Dijon is the best for early forcing, the others are better adapted for covering the roof of the Rose house, to which might be added Céline Forestier.

For early forcing, to bloom in the depth of winter, the following free-growing, profuse-flowering and charming varieties will be found invaluable—Safrano, Isabella Sprunt. Niphetos, Duc de Magenta, and Louise de Savoie. The following varieties, grown in the same house as those to bloom in midwinter, bloom freely a little later with us—Alba Rosea, Rubens (a fine old Rose), Adrienne Christophle, Goubault (a very free Rose in spring), Mad. Falcot, and Devoniensis—not the climbing variety. Then following these are Adam, Homère, Jules Margottin, Marcelin Roda, Marie Van Houtte, and Catherine Mermet. Many of the varieties of Teas when subject to early work soon die out, while others refuse to grow—for instance, Aline Sisley, Anna Ollivier, Duchess of Edinburgh, Bougère, Montplaisir, Perle des Jardins, and others do not succeed if subjected to much unnatural forcing. Many do well in pots and also planted out where they are allowed to grow on naturally. The first men-

tioned in our list for the Rose house bed are unsurpassed for those desirous of having their delicate and fragrant buds, which rank without doubt first amongst choice flowers at this season of the year.—WILLIAM BARDNEY.

ESTIMATES OF EARLY PEARS.

THE idea of engraving a well-known standard variety of Pear, and inviting opinions of its merits as compared with other varieties which ripen at the same time, is an excellent one which I hope will be carried out to the full extent it deserves, as I cannot imagine any other way of getting the required information in a form which will enable us to place the true value on it. I hope everyone who can, will contribute his mite of practical information on this all-important subject; but let us each time confine ourselves to a very small portion of the ground which has to be covered. Never mind about repetitions of local circumstances; we must have them in a condensed form with every communication, and at least the name of the county in which the writer lives; the full address where it can be conveniently given will be useful.

For the present we are to confine our attention to the season which precedes and includes the ripening of Williams' Bon Chrêtien. I cannot of my own practical knowledge at this place (and remember that is all that is invited) give an opinion of the other varieties which ripen at the same time; but I must say that if there is a better Pear for the season than the one under consideration it must be good indeed. Possibly, however, the musky flavour, so conspicuous in this variety and so much relished by most people, may be objected to by a few, and it is but right that these few should be treated with

respect.

Williams' Bon Chrêtien requires to be gathered before it is ripe, certainly as soon as there is the least change of colour at the eye of the most forward fruits; and, like all early Pears, it wants using on the day that it becomes fit for the table. The soil here is very heavy, resting on the stiffest of clay. Trees on the Quince stock do not last long; and although we are sheltered on the east by a well-clothed hill some 300 feet high and well wooded on the north side, the south-east winds in spring are very destructive. I do not consider the situation favourable for Pear-growing; but I must own that it has hardly had a fair trial, as owing to frequent changes before I took charge the garden abounded with young trees without names, most of which have now proved useless, but which I could not remove till they had been tried. I have Williams' Bon Chrêtien as a standard, as an espalier which is now allowed to grow rather wild, also a small plant on a wall with east aspect, and a larger one on a north wall, all on the Pear stock. The fruit on the standard and espalier come very much spotted; that on the east wall is the cleanest, largest, and best coloured, but is soon over; while that on the north side of the wall is rather shy in fruiting, but the fruit is good, generally without spots, and lasts in condition the longest.

Jargonelle is the only Pear I have which precedes Williams' Bon Chrêtien. There is a standard in the orchard and two large horizontal-trained trees on the east aspect of a wall. It is best on the wall at present, but I do not despair of growing it well as a standard, which form suits it best, as it bears best on the ends of the shoots. My trees of this are also on the Pear stock.—WM. TAYLOR, Wiltshire.

ALTHOUGH I was one who advocated an election of Pears, and endeavoured to prevent lists of varieties being sent in a desultory manner so as not to prejudice the election. I am now quite convinced that the plan projected of discussing the merits of the best varieties will be more useful, and certainly much more interesting, than what I may term a bald election compiled from imperfect collections.

Brevity, I presume, is advisable in estimates of the varieties submitted last week. As to locality, my experience during thirty years of practice is wide, having been gained south of London and north of York. I will take the south Yorkshire district, and state that over an area of at least 200,000 acres not exceeding 200 feet elevation, that as an August Pear the Early Harvest (Amiré Joannet) will succeed as standards on the Pear stock where the soil is deep and good and the position sheltered from the norfh and east. On light poor soils the fruit cracks. The Cluster Pear is not so good, the fruit being so small and often "woody." Doyenne d'Eté succeeds well as a pyramid on the Quince. For quality the last-named is the best

of the three; for quantity, the trees being large and healthy, the first. Grow both.

Of the August Pears, so called, Jargonelle, Citron des Carmes, and Williams' Bon Chrêtien are indispensable. They all succeed on the Quince, I will not say as close pyramids, for they dislike severe pruning. Plant them well and let them grow, and they will yield good crops of useful fruit. They are equally adaptable for walls, espaliers, and in very sheltered situations they also on Pear stocks make profitable standards. I have only grown Beurré de l'Assomption and Souvenir du Congrès on a wall having a south-eastern aspect; the former is not so early as I expected, ripening in September, and the latter is decidedly later than Williams' Bon Chrêtien. Both are fine Pears of superior quality. Beurré Giffard is a free-growing and good Pear in the north-east of England. I have named sufficient for most growers, and I pass by the others submitted

on page 487 as being less useful for the district named.
I may add that I do not attach so much importance to the "rainfall" as some do, as I have proved, to my own satisfaction at least, that a fall of 20 inches in the low-lying flat east coast. where rain drains away slowly, is equal in watering power to 40 inches in hilly districts, where the water passes rapidly

away .- A NORTHERN GARDENER.

OF the July Pears, the best I am acquainted with are Doyenné d'Eté and Amiré Joannet. The first I consider as being the best and most generally useful. They are not much grown in this district, as it is not suited to very early Pears; but in the midland counties, especially Leicestershire and Stafford-

shire, they are both extensively grown.

In the country villages around Leicester very many large old trees of Amiré Joannet are to be met with, which bear most abundantly, and the fruit is sold in large quantities in the markets. It is, however, to be regretted that young trees are seldom seen, the reason probably being that the tree does not appear to bear freely in a young state, and hence is not freely planted. The soil and climate of Leicestershire appear suited to Pear-growing, it being mostly of a light friable nature on a sandy or gravelly bottom, into which the Pear roots freely and seems quite at home.

In the district around Sheffield the soil is of a stiff tenscious character, with a clay or rock bottom. In this soil the Pear makes vigorous growth, but seldom or never ripens and matures

that growth properly.

Jargonelle is the best early Pear grown here, and is most

Jargonene is the best early rear grown here, and is most prolific on unpruned and untrained standards, although the fruit is not so fine as that grown on walls.

Upon the closely pruned pyramid trees which are grown in most gardens around here very little fruit is produced, and little is had from the trees excepting the annual crop of wood. Citron des Carmes and Williams' Bon Chrêtien are also fairly well grown in this neighbourhood, the former as standard trees and the latter on walls under glass. With us in an unheated house Williams' Bon Chrêtien bears freely every year, and generally produces very large and fine-looking fruit, and even there they are seldom in condition before the middle or end of September.—W. K. WOODCOCK, Sheffield.

I WAS glad to see the idea put forth of determining the relative merits of different Pears in various districts, which will without doubt prove more useful than an election conducted on the same principle as the late one on Roses. No kind of fruit is so worthy of cultivation for dessert purposes as the Pear, and none so widely influenced by soil and climatic influences. Our collection is very limited, and it is requisite that it should be, for many good and standard varieties, which in more favourable localities are excellent, are here poor and useless. July Pears in this locality are entirely out of the question, and Doyenné d'Eté does not ripen with us until the end of August or beginning of September. It is upon the Pear stock, and trained as an espalier. It is first-rate in quality, especially so in rather wet seasons. Our soil is of a light sandy

nature, about 3 feet in depth, resting upon red sandstone rock.

The Jargonelle on the Pear stock with us ripens well on a west wall, and is for this district one of the best early Pears. On a wall much care is necessary in producing a crop, as it fruits best upon forcing wood, and is therefore better adapted for growing as a standard without the use of the knife. This Pear is largely grown as standards in the fertile valley of the Tyne near Hexham, and in the neighbourhood of Boston and Spalding in Lincolnshire, where it flourishes and fruits abundantly. Beurré Giffard then follows, and as far as my experience is concerned I should certainly recommend it to be planted in East Lincolnshire either as a pyramid on the Quince stock or on the south wall. Williams' Bon Chrêtien is without doubt an excellent Pear, but in this neighbourhood of Liverpool is very shy of bearing fruit, and with us a crop is very uncertain. As a standard both in the south and many parts of Lincolnshire it is of unrivalled excellence. It must be gathered before it changes colour on the tree and ripened in the fruitroom, or else it possesses, comparatively speaking, no flavour.

—W. Bardney, Lancashire.

CONSIDERABLY upwards of a hundred varieties of Pears are grown here in a walled garden, and an orchard sheltered by a wood upon an upper slope of the forest ridge in the middle of Sussex, and about 400 feet above the sea level, with an average annual rainfall of about 35 inches, a decline of 10° in temperature in October, which is generally the most rainy month of the year, and with cold cutting winds of long duration in spring from. the north-east. The soil is on the Hastings sand formationpoor, thin, and light, almost pure silica very finely divided, with a close heavy subsoil of silica, and clay very retentive of moisture, and therefore thoroughly drained with ordinary 2-inch pipe drains, 4 feet deep and 30 feet apart. As the soil is so poor stations were made for the trees when the planting was done nine years ago. All the trees have become fine-specimens, and in the garden, where the soil adjacent to the stations has subsequently been repeatedly enriched with manure, they are in a satisfactory condition of healthy fruit-fulness; but in the orchard, where the subsequent enrichment of the soil has not been so thorough as could be wished, canker has done much mischief to some of the trees—another instance of many known to experienced fruit-growers that canker always attacks trees in a poor thin soil.

There are pyramids on both Quince and free stocks, palmette verriers on walls, and as espaliers on free stocks, and diagonal cordons on Quince, and many of them double-grafted. All of them have not yet fruited, but most of them have, and I am glad to say many prove worthy of a place in this paper. The following are the best early Pears that have yet fruited

Summer Doyenné (Doyenné d'Eté), cordon on Quince stock, east wall; fruit small, sweet pleasant flavour; ripe early in. August, is a free bearer and a useful early variety.

Desiré Cornelis, pyramid on Quince; fruit above medium size, delicious rich flavour, very sweet and juicy; is a free

bearer, ripe end of August.

Summer Beurré d'Aremberg, cordon on Quince, east wall; fruit of medium size, of fine flavour, very rich, sweet, and juicy;

a valuable addition to our September Pears.

Williams' Bon Chretien is worthy of the post of honour assigned it on page 487, for I have seen it in all sorts of situations, and the fruit has been invariably good. Excellent fruit of it has been gathered from a wall tree on the free stock, another wall tree on the Quince, also from pyramids on both stocks.

Comte de Lamy, cordon on Quince, also pyramid on Quince; fruit from both of the highest excellence, of medium size, very sweet, rich flavour; free bearer; ripe end of September.

—E. LUCKHURST.

AMBROSIA is one of the best early Pears here, coming in before Williams' Bon Chrêtien grown as an espalier 20 feet from the garden wall. It is a great bearer, slightly musky, and flavour excellent. I have heard judges say that it was the best-flavoured Pear grown. Be that as it may, I consider it the best early Pear. Williams' Bon Chrétien, grown on espa-lier 20 feet from the wall, one of the best Pears grown, bears regularly and well; a great favourite. Doyenné d'Ete, a fairly good early Pear, is not a good cropper here on espalier or pyramids. Jargonelle on walls east and west aspect bears well, and is of excellent quality. Souvenir du Congrès does fairly well as a pyramid, but has not yet quite established its reputation with us, and the same remarks apply to Beurre de l'Assomption.

The situation is very flat, about three miles from the Lincolnshire Fen, from 20 to 30 feet above high-water mark. The average rainfall for the year is 26 inches, although the rainfall was much more last year, and also much above the average this year. Soil a calcareous limestone not above I foot deep originally, but prepared for fruit trees, and well drained. Pears in general do well on the Pear stock, but do not thrive on the Quince. I have tried the Quince on walls all aspects,

espaliers, pyramids, and bushes, but in only one case did | Green and bright, as the name implies, its whole beauty consucceed, and that was Beurre Hardy as a pyramid.-D. LUMSDEN, Blocham, Lincolnshire.

PEARSON'S GOLDEN QUEEN GRAPE.

As a new Grape still on what might be termed its trial, I think it would be interesting to know what satisfaction this Grape is giving this winter. Last year some of your readers complained of it not keeping well, but this is contrary to my experience of it. The late Mr. Pearson had a high opinion of this Grape, as he thought its extreme hardiness, free-growing, free-fruiting, late-keeping, and good flavour were all such conspicuous qualities. The result of my experience corroborates this opinion. At the present time we have some bunches hanging in a cool house as fine and clean in colour, &c., as the best Muscats. As a late white Grape to use from November to March we think a few Vines of this variety would prove most useful.—A KITCHEN GARDENER.

CHRISTMAS ROSES.

THERE is something peculiarly charming in a flower which has grace and delicacy and yet can endure the keenest blast of an east wind and our most intense frost. Such is the Christmas Rose. Whoever thought of giving it that name must have loved the flower itself, for he has contrived to join in one, two words with the happiest associations. But the Hellebore deserves its common appellation thoroughly. It is true it has mone of the fragrance of the summer Rose, and yet it has a sweet gentle perfume which is very pleasing; and it has another good qualification—it lasts an immense time as a cut dower in the winter nosegay. Indeed that is the chief use which can be made of it, for in the depth of winter it is hardly possible to enjoy an outdoor plant. The best way to treat it, if it is to be allowed to flower out of doors, is to grow it in grass; the flowers will then come much purer and brighter than if it is grown in the border. But on the whole it is better to place a handglass over the plants to protect them from the splashing of mud by heavy rain. So covered they will come on slowly, and flower more abundantly and have larger blooms than plants kept in pots. But in order to make sure of them at Christmas it is quite necessary to pot them and keep them for a month or so in a gentle heat; you can thus time them to flower just when you like after once the buds are formed. Some people leave them planted out all the summer and pot them in 6-inch pots in the autumn, but I am inclined to think that it is better for the plants not to be disturbed, but to keep them in large pots all the year; in this way they thrive well if they have plenty of water in the summer and are placed in partial shade. They will continue yielding their delicate blooms under such treatment from the latter end of November till the end of January, and then the outdoor plants are ready to succeed them. They like good supplies of liquid manure, which may be given liberally without any stint.

But while the species Helleborus niger is so useful, its larger variety maximus is still more valuable, the flower being much more beautiful and the foliage more handsome; but the smaller one rejoices in being the pet of "my lady" at the Castle. This may be because it gives more abundant flowers and adapts itself more to forcing operations; but it is a pity that the large

wariety is not more generally grown.

With a little trouble I should fancy that very good crosses saight be made between the various species. It is true they do not flower together, but that might be arranged with a little care, and I fancy the result would be worth the trouble. H. abchasicus is a beautiful plant and does well in a rockery. It produces seed freely. I saved some ripe seeds from my plant of it last year and sowed them at once, and I see that they are now just beginning to germinate. It is necessary to have great patience with some seeds. I was convinced that these were good and must grow because I saved them myself from fine well-filled pods; but it is only now, after about six months, that they are beginning to reward my patience. The only two wild species, H. viridis and H. fœtidus, are neither of them common. I have found them apparently growing wild, but it was, I believe, after the fashion of those garden plants which, scattered round, marked the spot where once

"The village preacher's modest mansion rose."

They grew in the hedge where a garden had been. Viridis is a plant well worth growing as a picturesque rockery plant.

sists in the manner of growth and in the various shades of green in flower and leaf.

The genus Helleborus is nearly allied to another little winter flower, I mean the Winter Aconite, Eranthis hyemalis. Allied in race, they flower in the same dark gloomy season. If the Christmas Rose is grown in the grass it would be well to have masses of its relation by its side, for it is equally happy in such a situation, and its round fingered leaves look well when the bright yellow flower is gone. The latter is of course no use for gathering, unless it is ruthlessly dug up, as some people dig up Crocuses for dinner-table decoration; so that it might often rejoice in being let alone, while its larger and more aristocratic cousin is carried off for the church or the drawingroom,-A GLOUCESTERSHIRE PARSON.

THREE USEFUL ORCHIDS.

IF we were confined to cultivating only three genera of Orchids, we would choose Dendrobium, Odontoglossum, and the vestita section of Calanthes. By selecting suitable species from the first two genera, and adding Calanthe vestita Veitchii, C. vestita rubro-oculata, and C. vestita luteo-oculata, choice Orchid flowers may be had "all the year round." As winterblooming Orchids the three Calanthes named are unsurpassed for decorative purposes. The flower spikes remain fresh a long time after being cut, and three or four of them along with a few fronds of Maidenbair Fern placed in a suitable glass or vase form a most graceful object. There are two varieties of Calanthe Veitchii in cultivation. The flowers of one are lighter in colour than those of the other. The darker-coloured variety is considered the better of the two. Both varieties, however, are beautiful. Where choice flowers are in demand in winter these Calanthes should be cultivated in numbers.—B.

THE SHORTEST DAY.

BEFORE these lines are printed we shall have passed the ortest day of the year. What an amount of meaning lies shortest day of the year. in these few words, especially to gardeners! They may not, it is true, affect much the mind of the head gardener to some great nobleman or wealthy commoner who has an acre or so of glass under his charge; they may not excite any interest in the mind of him who, at this season, can stroll through his Camellia house and see hundreds of grand blooms in the perfection of form on the one hand, and the most glowing colours on the other; nor of her who spends her time wandering in the stove house, where the most glorious Orchids from Brasil caress her hair and kiss her face as she strolls along.

No; all these may care nothing about the turn of the days. But what do these words convey to the general public, the teeming millions of our cities, the hardy countrymen who till the soil? Above all others, what thoughts do they suggest to the occupants of lone country parsonages, who during these

winter months are, as it were, buried alive?

The shortest day is passed, and causes a feeling of great pleasure to me, who live far away from town, miles removed from a railway station, a mile or so it may be from a decent high road. "You ought to be let down by a rope such a road as this," says one visitor to the writer of these lines; "it is scarcely safe to venture down in the ordinary way." And so the involuntary recluse who inhabits these "wylds" looks out on the landscape, and feels as if life were a little bitter to him, that so far as he can see he thinks he may answer Mr. Mallock's question, "Is life worth living?" with a decided negative, for what prospect meets his eye?

The beds in front of his window are empty. Here and there a miserable broomstick sort of standard Rose presents a few for-lorn leaves, which are as much like what they are in summer as a broken-down cab horse is to a thoroughbred racer. As he looks the wind causes a dilapidated creeper to blow against the window, and as he listens he thinks of the words that suggested the opening of Beethoven's C minor Symphony, "So Knocks He must, he thinks, get out of this or he shall go mad. He will go to town and forget the weather, and the bare beds, and the dismal country. He arrives there, and finds London enveloped in a dense fog. At noonday it is as dark as night The gas is burning all day at his club. He cannot stand this He can, at least, see to read at home during daytime without artificial light. So he hurries home, to find the weird symphony still being played. He is in despair, when suddenly he remembers a fact that he had for the moment forgotten. He calls to mind the day of the month, and finds that the shortest day is passed, and that now things must soon mend.

He may not see that the days lengthen at first, but he knows that they are really doing so; and this conveys the sweetest comfort to him. Let the rude wind bluster away, let the trees bend their heads in terror at the blast, let the soaking rain swamp his garden, let the prospect be ever so bleak, he can stand it all now, for the days are lengthening, and each time he rises from his bed he knows that he is one day nearer

Soon in his garden Nature will tell him of spring's approach. The Hellebores, the old Christmas Roses, will begin to look a little green at their base, however dead the leaves may seem, and in a few days there will appear to the observant eye the first signs of a bloom bud. As soon as he sees this he takes comfort, for he knows that this is the earliest forerunner of spring; that those large white blooms, though they rise on a carpet of mow, are leading the vanguard of Flora's army, which is come to wage war with winter; and though the fight may be arduous and long, though the keen frosts may decimate with the rigour of their attack these fair flowers, yet again and again will the Hellebores advance to the front and hold their own. Soon they will be joined by other regiments. The Primroses will come to their help, while the Snowdrops will raise their white standard and fight for Queen Flora; and when these have gained the day he knows the cause is really won, although the fight may be waged for many weeks.

But see, the days are now visibly lengthening, and the sun is getting higher in the heavens. While a few days ago the lamp was lit at four o'clock we can now read to nearly five; and hark, Is not that a bird? Yes; a robin is singing its evensong to the Creator of all things before tucking his brown little head in his scarlet breast for the night. Yes, the bravest of birds, the faithful little watchman of the house, which never leaves us be the weather what it may, is one of the first to tell

as the days are lengthening—the shortest day is come and gone.

Ah, now; the case is not so hopeless. Now we can, without feeling sick at heart, turn our eyes to the book shelf, and bring down our volumes on Roses; or we can dive in a drawer and bring out what may be called our "stud book," the book in which we record the names and the numbers of varieties of Roses which we grow; or we can turn into the fruit room and have a look at the Gladioli bulbs reposing on the shelves. We feel them over one by one, and see if the frost has hurt them. No; the little stove has done its duty well. The bulbs are hard and dry, and we know that the time will soon come when we shall want to plant them. Now, too, we may take stock of our Rose labels, and see how many more Alfred Colombs and Marie Baumanns we must order to be printed. while we are doing this a visitor is announced. "Oh! only the carpenter." "Well, what do you want?" you ask. "Please, sir, work is scarce just now, can you give me a job? Something I can do at night during the long evenings will suit me best." We stand for a moment in doubt, when suddenly we remember the Rose boxes. They will want overhauling. They are so knocked about on the railways. Some want repairing, all want painting; so we hand them over to the carpenter, and send the man away happy—for the time at least. When the boxes come back the days are certainly much longer; you can hardly believe the man really wanted a job during the "long"

All these little occupations, trifles though they be, help to pass the time of the gardener, and serve to keep up his spirits during the dismal months of the year. But above all other thoughts, the one that breathes the sweetest air is the convic-

tion that the shortest day is past.

"But what is all this?" I hear some of my readers ask. "Surely 'WYLD SAVAGE' has had his mane combed to some purpose, and fed on gruel and water, before he wrote so sentimentally." "No, he's not, sir; he's in his usual health. He may be growing old, but he has most of his teeth and lives much the same as ever; he's only been struggling after a ray of hope to cheer in a dreary season at a time when dulness should be abandoned; and if you think the struggle is indeed a failure -well, it is a time of the year when Christmas boxes and other sentimental customs (which have a flavour of reality about them, too, to most of us) are in vogue, and so for once, con-sidering the season, please excuse a—WYLD SAVAGE.

CHRISTMAS FLOWER SHOW AT EXETER.—In Mesers. Lucither in regard to quantity, quality, or keeping propensities.

Woodman has a fine assortment of flowers. In one house thereis a magnificent display of five hundred blooms of the wax-like Lily of the Amazons, the Eucharis. Near at hand are delicate Orchids with crimson or orange-tinted centres, and in an adjoining house the crimson-crowned Poinsettia pulcherrima provides valuable material for decorative purposes. Some scores of Hyacinths and many of the great Lilies of the Nile are also in full bloom, both having been forced on to meet the Christmas demand. Visitors, however, will feel most inclined to linger in the long house of glass, the atmosphere of which is laden with the perfume sent forth from the varieties of Roses which are here blooming in summer-like profusion. The great Camellia house, where some of the trees are fifty years of age, is noted throughout the west of England, and most of the trees are now crowned by white and scarlet blooms. The buds are to be numbered by thousands, and but for the prolonged absence of sun many more blooms would have shown themselves than have yet appeared. One of the show houses has for a month past been occupied, and is still filled, by a great-variety of Chrysanthemums, and these in themselves form a flower show well worth seeing. Most attractive are the Japanese varieties, each flower looking like a bunch of deli-Cately coloured shavings. James Salter, Gloire de Toulouse, Fair Maid of Guernsey, Elaine, and Abd-el Kadir are among the most striking varieties, and all are especially valuable from the length of time which they remain in flower; while among the incurved varieties the beautiful white blooms of Comtesse: de Granville cannot but excite admiration,—(Western Times.).

IRIS FŒTIDISSIMA VARIEGATA.

WE seldom meet with this variety of Iris, yet it is one of the most useful hardy fine-foliaged plants in existence. The variegation usually consists of a narrow stripe of greenishwhite colour, the remaining two-thirds of the long narrow leaves being of an intense green occasionally faintly striped. This variegation although not showy is very persistent, and taken into conjunction with the lightness of growth and the fact that no extremes of weather appear to affect its well-doing, renders it a very desirable and useful plant, whether it be for employing with either the summer or winter bedding plants or for the decoration of verandahs and corridors. It is easily propagated by division whenever the plants are wanted—any portion of its rhizomatous stem can be easily moved, and soon forms a strong clump. We have used quantities of it at different times, taking up a few strong clumps when wanted and dividing them, placing them either in clumps for centres of beds or lines, or else singly dotted among Myo-sotises, Silenes, Pansies, and Violas. It is a most accommodating plant, thriving anywhere; we have it on hot banks in very poor soil, and under trees, in the front line of shrubberies. Those planted in a stiff and very clayey soil grow the strongest, soon forming clumps from 2 to 3 feet through. We also usually lift and pot some for use where hardy plants in pots are wanted The bloom is very insignificant, but the above-mentioned good qualities entitle it to a greater share of attention than it at present receives.—W. IGGULDEN.

DIGGING AMONGST FRUIT TREES.

I THOROUGHLY agree with "A KITCHEN GARDENER'S" system of manuring fruit trees, which is recorded on page 443. No better practice could be adopted than that referred to. We never disturb the ground amongst any kind of fruit trees except when root-pruning, and that is only once in three years. We root prune a few trees every year, so those that are done this year will need no further attention in this respect until the autumn of 1882. Our largest square of Raspberries has been planted seven years. Since then a spade has never been employed amongst them, and the result is strong canes and good crops. Strawberry ground receives plenty of fresh manure trenched in previous to planting; after that nothing is done to disturb the surface, but a good dressing of manure is applied every autumn, which remains on till the fruit is gathered; then when the general clearing away of weeds and runners takes place the Strawberry refuse is raked off, and the work is done until the ground is hardened by dry weather or frost, when the new dressing is wheeled on. Apples, Pears, Gooseberries, Currants, and Raspberries are treated in a similar manner, and we have no reason to complain of our crops

amongst surface roots annually? As "A KITCHEN GARDENER" very correctly observes, the destruction of the surface roots must tend to render trees fruitless, as those roots must be the principal agency in producing fruitful wood.—H. ELLIOTT.

THE METEOROLOGICAL SOCIETY.

THE usual monthly meeting of this Society was held on the 17th inst. at the Institution of Civil Engineers: Mr. C. Greaves, President, in the chair. T. Buckland and G. Wigner were balloted

for and duly elected Fellows.

for and duly elected Fellows.

The following papers were read:—"On a Sandstorm at Aden July 16th, 1878," by Lieut. Herbert H. Russell (8th Regt.); "On a new form of Hygrometer," by G. Dines, F.M.S. This is a modification of the hygrometer which was first described at the British Association Meeting in 1872. The outside dimensions of the instrument inclusive of the wood casing, are about 10 inches in length, 3 inches in breadth, and 2 inches in depth. The upper part consists of a vessel of thin metal, 6 inches long, 2½ inches troad, and 1½ inch deep. Beneath this and detached from it, but connected by a pipe, is a small chamber 2½ inches long and 1½ inch deep from back to front, standing about a half inch more forward than the vessel above, and with a piece of thin black glass in front. Inside this chamber parallel to the front is a division which separates it into two parts. This division does not extend quite to the top of the chamber, and is slightly turned over towards the front so as to allow water to pass over it, and to over towards the front so as to allow water to pass over it, and to induce the latter to flow more directly to the centre of the front of the chamber. The upper vessel is connected with the bottom and back part of this chamber by a small pipe, with a tap to it which is turned from the outside. The front of the chamber has a pipe attached to the bottom, passing upward in an inclined direction, and terminating at the outside in a small lip or spout. A thermometer with the bulb inside and over the front of the A thermometer with the bulb inside and over the front of the chamber passes through an indiarubber collar at the top of it, and is protected by a groove sunk in the face of the wooden case. The action of the instrument is as follows:—Water of a lower temperature than the dewpoint is placed in the upper vessel, and, on the tap being turned, flows into the back of the small chamber, and thence passing over the top of the middle division flows downwards, cooling in its passage the thermometer and black glass, and eventually escapes by the small spout on the right side of the instrument. As soon as dew appears on the class the flow glass, and eventually escapes by the small spout on the right side of the instrument. As soon as dew appears on the glass the flow of the water is stopped by means of the tap, and the temperature is read off by the thermometer. When ether is used it is poured into the small shoot, passes down the inclined pipe, and remains in the front part of the chamber. A piece of metal tube ground so as to fit the inclined pipe tightly and with an aspirator attached is then inserted, and the dewpoint is ascertained in the same way as by Regnault's hygrometer. "The Diurnal Range of Atmospheric Pressure," by R. Strachan, F.M.S. The author has Atmospheric Pressure," by R. Strachan, F.M.S. The author has compiled a table of constants from thirty places in various parts of the globe, which support Sir John Herschel's remark that "the diurnal oscillation of the barometer is a phenomenon which invariably makes its appearance in every part of the world where the alternation of day and night exists, and that within the Arctic Circle the diurnal dies out, or rather merges in, the annual oscillation." "Note on a Curious Fracture of a Solar Radiation Thermometer," by G. M. Whipple, B.So., F.R.A.S.

Mr. R. H. Scott, F.R.S., exhibited and described a new form of sunahine recorder, which is to be used during the coming year at a considerable number of stations distributed over England.

THE CULTIVATION OF THE GLADIOLUS IN THE MIDLAND AND NORTHERN COUNTIES.

A CORRESPONDENT on page 440 asks a question which, as he himself suggests, is difficult to answer without knowing more of the conditions with which he has to deal, especially the county and the nature of the soil. It is very tantalising to those who work under the difficulties of bad climate and bad soil to read in your Journal descriptions of success in open-air gardening, which they know it is hopeless for them to attempt to imitate. Those who write gardening directions for the public are too apt to forget that rules of cultivation which suit Kent or Cornwall may be quite inapplicable to Northumberland or Lancashire.

I have grown the Gladiolus (gandavensis varieties) in different places for more than thirty years. I have read every-thing I have been able to find about its cultivation. I have at different times taken the advice of the most successful growers, and have bought bulbs from at least twenty of the leading dealers, and the conclusion at which I have arrived is that the climate of midland and northern England is suited for the cultivation of the Gladiolus only in the same way as the Hyacinths are grown there; those who grow it must be contented to see their stock lessen and deteriorate

from year to year, or must replenish it annually by fresh purchases. At present I live on the clay soil of Cheshire, and I persevere in planting three or four hundred Gladioli every year. About two-thirds of these flower, and about half of those which flower seem to ripen healthy bulbs, sometimes two or three bulbs each, but these do less well the next year, and if the stock is not replenished it gradually dies out.

As regards the question of leaving them in the ground, I have never ascertained exactly to what amount of frost a Gladiolus bulb may be exposed without being killed, probably either in or out of the ground it might stand 10°. In December, 1860, I lost through carelessness a large stock of Gladioli from frost, though they were stored on the floor of a bedroom; but those who are careful can protect them from frost by litter, either in the ground or out of it. My habit has been to leave part of my Gladioli in the ground without any protection, and to lift and store part of them, and I have never seen any great difference in the results, both plans being as I have said, failures. Last winter, it is true, killed nearly all that were left in the soil, but this was my own fault; those I lifted were finer and healthier in appearance than I had ever had them, but the result of this season has been miserable. I had not two hundred good flower heads out of five hundred bulbs

planted.

No doubt the chief cause of failure to grow the Gladiolus successfully in Cheshire is the deficiency of summer heat the average summer temperature being several degrees lower there than in the south of England. The bulbs are not properly matured. Soil has something to do with it, but my flower beds are all perfectly drained at a depth of 3 or 4 feet, and I have tried every composition of soil and every aspect which can be recommended. It is true that any artificial soil is to some extent starved and chilled by the surrounding clay however well it may be drained; but in gardens a few miles from mine where there is no clay the Gladiolus behaves just as it does with me, so I lay the chief blame to the climate. The history of our Gladiolus beds is much the same from year to year, varying slightly according to the season, and it is as follows:—The bulbs are planted from the middle of March to the middle of April, attention being paid to the directions of the best growers. About one-tenth never appear above ground at all, in one-fifth of the remainder the shoot turns brown and decays at the base when 3 or 4 inches high. Those which survive that stage generally make flower buds, but many either become brown and wither before coming into flower, or sudstage of failure to experts for examination; sometimes the verdict is "No assignable cause," sometimes "The bulbs seem quite healthy, and will probably succeed in a better soil and climate." I may add that in spite of all these troubles, which I have not exaggerated, my garden is famous in its neighbour-hood for its Gladioli, and I am constantly asked by neighbours both where to get the bulbs and how to grow them. I may also say that I have tried planting side by side a bed of bulbs obtained from M. Andrieux of Paris, and from Mesars. Kelway of Langport—French-grown against English-grown, without any observable difference in the results. I am curious to know whether any gardeners in the midland and northern counties of England can obtain much better results in the cultivation of the Gladiolus.-W. Dop.

CHAPTERS ON INSECTS FOR GARDENERS.—No. 1. NEW SERIES.

In the order Orthoptera (i.e., "straight-winged" insects, from the usual mode in which the under wings are covered by the upper) are arranged some of the species that are of very large size, and which surpass all their brethren in grotesqueness or in singularity of shape. There are not here the multitude of species noticeable in other groups, as, for instance, amongst the flies and the beetles; but the Orthoptera will compare favourably with any other insects in according to the increase and with any other insects in regard to their powers of increase and their great agility. The destructive effects produced by several species have made their name expressive of alarm in those countries where insect life is at the full flood, owing to favourable influences of time and sun; and the British gardener may congratulate himself that if, in these temperate regions, his plants have to suffer at times from sudden changes, he escapes, through his location, hosts of insect enemies capable of doing damage which, unless seen, can hardly be credited. Doubtless there is, however, a compensating force in Nature, since where plant life is often interfered with by insect foes or by atmospheric disturbances the damage is in many cases speedily

repaired by a new growth.
In the Orthopterous order the insects undergo the usual transformations; but in the pups, or third stage, they are nearly always active, so that the difference between the larva and pups is only that the latter has upon the back the rudi-ments of wings. Whoever has watched the evening frolics of a party of cockroaches (Blatta orientalis), commonly called "blackbestles," must have noticed the fact that as they run "blackbestles," must have noticed the fact that as they run about they seem equally agile, though varying in size, while some exhibit the wings partly developed. It is one peculiarity of these pests that in their domestic life with us the adult cockroaches never make use of their wings to fly; possibly these sid them in executing the lesps from walls they sometimes perform. Then, again, the newly-hatched little creature belonging to this order has altogether a near resemblance to its after self; there is no difference, such as we observe, between the magget of a fly and the perfect insect. Some justification of the name "beetle," applied to certain species, lies in their possession of wings and wing-cases, but in the Orthoptera these overlap; in the true beetles they mostly meet in a line at the middle of the back. At the extremity of the body are at the middle of the back. At the extremity of the body are

Pig. 49.-Mole Cricket.

two bristle-like appendages, which are very long in some of the crickets. A glance at the head of a specimen, even without the aid of a magnifier, suggests the predactous character of this order. The jaws and maxilie are well developed; biting and grinding are both performed vigorously. Several species are, moreover, capable of inflicting a bits in the human akin

which will cause sharp pain.
We pass by here the curious insects to be inspected in our museums, a few of which occur on the continent of Europe but the majority in tropical countries, called Leaf Insects and Walkingsticks, also the Mantides, sometimes regarded with superstitious reverence because, when hunting for their prey, ey assume the attitude of prayer. Our English species are divisible simply into two groups — the little group of the runners, and the larger group of the leapers, these being again divided. The Blatte, or cockroaches, of the first group are best known by B. orientalis, a name significant of the supposition that this odious species came to our islands from the East. There is strong probability that it was imported from somewhere—a minor mischief arising from our commerce. Now, at all events, the insects have distributed themselves throughout the country, and instances have been reported to us where the cockroach has travelled from the kitchen into hothouses and conservatories. In such places, beside the offensiveness of their presence, intruders have been noticed to attack some plants, usually succulent species. The late Edward Newman has noted the circumstance, as a redeeming quality in their character, that cockroaches seek out and devour the malodorous Cimex lectularius; but he asserted there was no foundation for the statement that cockronches and crickets will not abide in

the same dwelling. So vivacious are cockroaches, that no ordinary measures suffice for their destruction, but they may be caught in traps by beer and then killed by heat. phorus paste has strange fascinations for them, frightening away afterwards, seemingly, those who have seen their brethren suffer from its effects. A peculiarity in the habits of the female cockroach is that she carries her eggs in a case or capsule beneath her body, and when this is matured the parent assists the young larve to escape from the shell. Cockrosches of various sizes may now and then be noticed quite white, indicating that they have just cast their skins, the new skin not having sequired hardness and colour. Besides this naturalised insect, we have several British species of cockrosch, less in size, and not so frequently observed. It is the habit of some to live under bark, some hide under stones or in masses of herbage; these are not, however, the cause of any damage in gardens.

Coming to the second division, the first family comprehends the crickets and the grasshoppers, with long antennæ and flat-tened wing-cases, with also a very remarkable musical instru-ment, which has been called a natural violin, complete with bow, string, and sounding-board. We are so accustomed to hear sounds issue from the mouths of the larger animals, that we naturally think at first, when we hear the chirp of a cricket, that the noise comes from the insect's mouth; and the old entomologists had an idea that it was caused by the rubbing together of the legs; some insects do, in fact, manage to produce sound in that way. But we will let Professor Westwood describe the vocal apparatus of the field cricket, which may serve as a sample of the family. "On the margin of the wing-cover," says be, "a thickened point is observed from which several strong veins diverge, forming angles. The strongest of these veins, which runs towards the base of the left wing-cover, is regularly notched like a file. The wing-covers being closed, this oblique bar lies upon the upper surface of the corresponding part of the right wing-cover, and when a tremulous motion is given to the wing-covers the bar on the left rubs against the bar on the right, and thus produces a vibration." The sound is echoed or increased by the whole surface of the wing-covers. The strength of these insects is proved by their ability to continue this motion of the muscles for hours, as anyone knows who has had the misfortune to live where house crickets "most do congregate." Misfortune ! did we remark? It is not that to all persons, for some do posi-tively like to hear the monotonous strictulation of the original Certainly we may more easily admire the chirp of the grass-hopper on a summer's day, though that may be wearisome if heard for too long a time. In all these species it seems that only the males have this gift of song, as poets call it.

But there are differences in voice, even amongst species nearly allied. The mole cricket (Gryllotalpa vnigaris), fortunately not common in Britain, has been styled the "Churr Worm," from its low monotonous, note while in attracture it much

from its low monotonous note, while in structure it much resembles the quadruped that has given it the more usual name. This insect drives extensive tunnels under the soil of kitchen or flower gardens in some instances, and they de-stroy plants, not only by the injuries produced through their biting operations, but by dislodging them from the soil. White of Selborne alludes to the damage done in his locality. Of late years, however, we have not heard much about the mole cricket. Its smaller relative, the field cricket (Acheta campestris) is also an excavator, but not so extensive a one, and it generally forms its burrows in dry fields. Frequently it preys upon other insects, but not sufficiently to merit the title of a friend to the gardener, which has been bestowed upon it. and this insect, probably, when young feeds chiefly on leaves, like most in the family. A metsorologist has observed that by a peculiar change in their chirp the field crickets indicate the approach of rain; possibly this is also true of the house cricket (A. domestica). Both are fond of moisture, and the latter, feeble as it looks, displays dexterity in digging amongst

The grasshoppers have shelving wing-cases; and, though the popular name assigns them a low position in the world, they are commonly found leaping, or at rest, amongst bushes and trees. None of them are troublesome to the horticulturist, nor even None of them are troublesome to the horizculturist, nor even to the farmer; but the largest English species (Gryllus viridissimus) which is about 2 inches long, and of a beautiful green tint, furnishes occasional paragraphs to country newspapers, being reported as a "locust." The eggs of grasshoppers are placed in the earth, the females being provided with ovipositors; from these the young brood appear in the spring. We have about a dozen species of the Gryllids; one or two are quite small and unable to fly, but in all the legs are longer and more slender than in the crickets.—J. R. S. C.

CAPSICUM PRINCE OF WALES.

Amongst other plants bearing brightly coloured fruits and berries, and that prove useful for decoration at Christmas time, this Capsicum is especially valuable. It is easily grown. Our seed was sown in April, but May would have been quite soon enough, and the plants were grown and shifted steadily on till they were in their fruiting pots, the best size apparently being pots 6 inches in diameter. When well established some were placed in a warm and what in some seasons would have been a sunny spot in the open, and others in a cool plant house. The former made but poor prograss, but the latter formed good heads about 5 inches high, no pinching being resorted to. The fruit sets freely, and hangs from every joint of the flat branching head; it is short, thick, and conical in shape, the colour when ripe being a bright yellow. We found it necessary to introduce some of the plants into heat to ripen the fruit; neither does the temperature of a cool house suit them after it is ripe. Solanum Capsicastrum set badly this season, and we have had to introduce the plants into heat to ripen the fruit for Christmas decoration.—W. J. O.

COST OF EXHIBITING ROSES.

I REGRET much the spirit in which "WYLD SAVAGE" has thought fit to reply to my letter in your number of the 11th inst. First he seems to object to any answer to his article in the "Rose Annual" being published at all in the Journal, and then accuses me (I cannot say of him, as he says of me, "in courteous language") of "giving no reasons, adducing no

The description of me, as "a correspondent perfectly unknown to him," I may dismiss as irrelevent to the question. I simply read his article, which is public property, and concluding that his estimate of expense necessary to be incurred by exhibitors was excessive and calculated to deter some at least from exhibiting, I thought myself well justified in endeavouring to show that by a different system this expense might be considerably reduced, and be brought within the reach of some who, while as fond of Roses as "WYLD SAVAGE" or myself, would find it easier to spend £20 or £30 than £100. Nor was this a matter which would keep a year. His article appeared at a time when Roses were being ordered, stocks planted, and Rose gardens prepared, in many cases doubtless with a view to exhibition.

- Your correspondent says in his letter that he gives no advice as to "when" the exhibitor is to begin to show; not in so many words, but he includes in his £100 estimate the expenses of exhibiting, and mentions the cost of travelling to Crystal Palsce,&c. What inference can be drawn from this but that these are shows the exhibitor is expected to attend, and this in the first year? for his estimate is all through that of establishing a collection for exhibition, not of maintaining it in subsequent

I confess myself much surprised by his success with newly bought Roses. I presume much must be attributed to soil; mine is very heavy, and it takes at least twelve months for Roses to establish themselves, and those I bud will surpass them even then. Let me quote from Mr. Reynolds Hole: "If you propose to grow Roses for exhibition you must grow them on your own stocks from buds." So if I err it is in good company. Relative to the question of such extensive disbudding, I wrote from experience and found only the effect mentioned.

Again, "I dispute his figures." Now the only figure I think which I dispute is the price of manure, and even in this matter I take his price, not my own, as the basis of calculation. Had I worked with my own price I should have diminished the sum charged by half; and even then, according to "KENTISH CURATE'S" opinion, have set it 40 per cent. too high. The price is simply a question of locality, and I am very much mistaken if my calculation is not nearer a general average than his. After all the question resolves itself pretty much into this: "Can you afford to buy all your Roses? and will those transplanted give exhibition blooms with you?" If you can answer these questions affirmatively, well and good; but if price deters you, or purchased Roses will not at

first thrive with you, I named a cheaper and more satisfactory mode of attaining the same result.

But to one of "WYLD SAVAGE'S" figures contained in his

But to one of "WYLD SAVAGE'S" figures contained in his letter to the Journal I really must demur. He talks about 25 per cent. of stocks as not having struck and 25 per cent. more as blown out. I have just counted off one hundred stocks of 1878, and find just nine blanks from death of stock or bad, and shall blame my own carelessness if I lose half a dozen more by the wind. The only question of cultivation, I think, in which I am at issue with him is that of manuring at the time of planting, and here I am not alone. I am supported by the National Rose Society, by Mr. Baker, Mr. William and Mr. George Paul—no mean authorities.

I hope I have succeeded in justifying both the writing of my former letter and its contents. Like "WYLD SAVAGE" himself I could have no other object than the advantage of the Rose-growing community, and especially the younger members. Thanks to him for the pleasure many of us have received from his notes on Roses, and a merry Christmas to him and all of them. I fear the new year will be one of disappointment, and that the frosts will have played havoc with many a garden, but let us hope for the best.—Duckwing.

WINTER LETTUCE.

WE grow numbers of these in various parts of the kitchen garden, and although they are covered over with flower pots, mats, straw, or fern, very many are destroyed. For this reason we are not depending much on such crops now, as we find it much better to have a supply under frames. When Melons, Cucumbers, &c., are cleared out of the frames in September a large number of Lettuce and Endive plants are lifted from the open borders and planted as closely as possible. A frame 6 feet by 8 feet will hold a large number, and a supply of fine, clean, crisp Lettuce is afforded for a long time. At the present time we have several frames full of Lettuces and Endive which have been covered over with lights, mats, and fern for three or four weeks to keep the contents from frost, and during the time of frost or snow we have only to push a light up or down to cut clean half-blanched Lettuce and Endive in much better condition than ever we can obtain them from the open quarters at this season.—J. MUIR.

NEW COLEUSES.

It is now about twelve years since Mr. Bause commenced at Chiswick those experiments in the hybridisation of Coleuses which proved so remarkably successful, and resulted in the production of a number of distinct and handsome forms. By the skilful intercrossing of seven or eight species, varieties were obtained greatly superior to their parents in a decorative point of view, the leaves being brilliantly and diversely coloured, and the margins elegantly crenated and incised. Attracted by such satisfactory results many other hybridists turned their attention to the Coleuses, especially Mesers. Bull, Henderson, and Cannell, whose annual lists of novelties have considerably increased the number of really useful forms; indeed, so abundant have they become that the public taste is in a degree satiated, and a new variety must now possess exceedingly good qualities to ensure a ready reception. Still, we cannot by any means afford to neglect these useful plants, for in the decoration of the conservatory during spring and summer they prove, with suitable treatment, of great value, the richly tinted leaves contrasting very agreeably with the green foliage of other plants. The Ooleus has also taken its place as an exhibition plant, and in the special classes devoted to it at most horticultural exhibitions remarkably handsome specimens are frequently staged, although in some cases excessive luxuriance and extraordinary dimensions instead of high colour and symmetry appear to be the object of the cultivator.

During the present year at least thirty good varieties have appeared in commerce, and of these eleven have been honoured with first-class certificates at the meetings of the Royal Hort-cultural Society and the shows of the Royal Botanic Society. The following varieties are particularly attractive:—James Barnshaw.—Of free growth, with fine handsomely marbled foliage richly marked with red, green, and yellow. Majesticus.—Very bright; large, tapering leaves, crimson in the centre and margined with yellow. Starlight.—Very distinct; leaves of a bright rose tint beaded with yellow, and undulated margins. Maude.—The ground colour of the leaves pale yellow, irregularly mottled and streaked with crimson and

green. Duchess of Teck.—Highly effective; the leaves purplish crimson in the centre, with a broad margin of bright yellow. Tricolor.—Foliage of a dark velvety maroon colour, lightened by a crimson midrib and a green serrated margin.—L. C.

ORIGIN OF WILLIAMS' BON CHRÊTIEN PEAR.

In your article (page 488) on Williams' Bon Chrêtien Pear you say it was raised by a man named Wheeler, a schoolmaster at Aldermaston. I desire to say the schoolmaster's name was Stair; my grandfather went to school to him, and my father, who is seventy-nine years old, remembers the original tree quite well. I live two miles from Aldermaston, and the old people about here know Williams' Bon Chrêtien by name as "Stair's Pear."—PADDLE.

NOTES AND GLEANINGS.

REFERRING to the EFFECTS OF THE FROST IN LINCOLN-SHIRE, Mr. Lumsden of Bloxholm Hall Gardens informs us that many shrubs are killed to the ground, all the varieties of Broccoli completely destroyed. Brussels Sprouts, Cottager's and Buda Kales have escaped, and do not appear to be much worse for the severe ordeal through which they have passed.

A CORRESPONDENT informs us that the FROST in East Norfolk has been very severe; old Cabbage stumps are killed to the ground, while Sutton's new Glazed-leaved Cabbage, and also their new Thick-leaved Cabbage, are likely to prove a great boon to many, as they are not injured in the least Cauliflowers and Broccolis are much injured, and many will soon decay.

ONE of the handsomest species of Scabious we are acquainted with is SCABIOSA CAUCASICA. It produces a large number of flowers from June to August, about 3 inches across. The outer florets are deep porcelain blue, while the inner florets are white, with the orange-coloured anthers exserted. It is a true perennial and quite hardy. Planted in the mixed border it is very showy and distinct.

"I CAN strongly recommend," writes Mr. W. Groves of Shortlands, Kent, "KARLY RIVERS PLUM. Last season my Plams were quite a failure with the exception of this variety. I am getting rid of others less worthy, and planting this—the most valuable Plum that I have."

EVERYBODY who possesses a rockery, or who cultivates alpine or choice border plants, should have Onomia Taurica, as it is exceedingly showy. The leaves are narrow lanceolate, thickly covered with rough stellate hairs, which are lovely microscopic objects. The thyrsi of flowers are produced very freely, supported on peduncles about 6 inches high, which at the floriferous portion is nodding. The flowers are about 1 inch long, with tubular corollas of a deep yellow colour. The sockery is the best place for it. We have had it remarkably strong in a well-drained sunny position, although we have also seen it in splendid condition in warm borders, notably a plant at Mr. Joad's of Oakfield, Wimbledon Park, which was crowded with flowers. It is not very plentiful owing to the difficulty experienced in increasing it. If cuttings are taken off about February with a heel and kept in a cold frame a good percentage of them will root, and we have also found that if some andy soil is laid at the base or middle of the plant the shoots will frequently root. It flowers from May to July. It is abundant in the hills of Tauria, as well in the Caspian Caucasus mountains, and has been introduced into this country nearly a century.

— DR. RICHARD SCHOMBURGE has published a list of the NATURALISED WEEDS in South Australia, which contains several interesting facts. Such well-known and troublesome weeds as Capsella Bursa-pastoris, Stellaria media, Senecio vulgaris, Sonchus oleraceus, Solanum nigrum, Rumex Acetosella, Urtica urens, U. dioica, and a few Grasses have spread very rapidly and are becoming great pests in some districts. Erodium cicutarium, Plantago major, P. lanceolata, and P. Coronopus have spread chiefly in pasture lands, and are stated to be greatly relished by cattle. Although the majority of species are natives of Europe a few have been introduced from Tasmania, the Cape of Good Hope, &c. The most remarkable of these is the Cape Dandelion, Cryptostemma calendulaces. It was first observed in 1850 on the banks of the Gawler River, but it is now "found quite two hundred miles toward the goth of its starting point, covering even the untimbered moun-

tain ranges to their summits." Cattle and sheep are very partial to it.

— MESSES. JAMES CAETER & Co. inform us (that after our reporter left the meeting) they were awarded a first-class certificate for the SCOTCH CHAMPION POTATOES submitted by them to the Fruit Committee of the Royal Horticultural Society last week. The Potatoes are referred to in our report on page 483.

WE have received the usual annual parcel of MESSES.
LETTS' DIARIES, which are adapted to every conceivable purpose either of the counting house, the library, the household, or the pocket. It is not only as diaries that they are valuable, but they contain much information of a general kind which is useful to everybody. We can strongly recommend them as by far the best of any we have seen.

— WE have received the PROGRAMME of the SECOND HORTICULTURAL EXHIBITION which is to be held at Buenos Ayres from the 22nd to the 29th of February, 1880. It is divided into four sections—1, Fruits; 2, Plants; 3, Vegetables; and 4, Miscellaneous. The Secretary is Senor Fernando Mauduit.

THE President of the Entomological Society of Ontario, in his annual address made before that body, stated that for some years past experiments have been made with various other substances with the view of finding a SUBSTITUTE FOR PARIS GREEN as a plant insecticide which would be less dangerous in the hands of the careless, and among them none have been used with greater success than common blue vitriol or sulphate of copper in solution, in the proportion of about an ounce to a pail of water, and applied in the same manner as the Paris green mixture. This article is worthy of, and will doubtless receive, a more extended trial, as its use under any circumstances would be attended with but little danger. For the destruction of household pests insect powder has lately attracted much attention, and is probably the most valuable agent we have for this purpose, and it is quite harmless to man and the higher animals. There are two sorts of this powder, known in commerce under the respective names of Persian and Dalmatian insect powder; the former is the powdered flowers of Pyrethrum roseum, the latter of Pyrethrum cinerarisefolium. The Dalmatian powder is most highly esteemed. The powder is diffused through the atmosphere by means of a small bellows, or insect gun, and in a very short time it brings house flies, cockroaches, &c., on their backs, and is equally effective on insects infesting plants.—(Prairie Farmer.)

A TRIO OF CHOICE HARDY PLANTS.

Androsace langiness.—Nearly all the Androsaces are very handsome little plants from alpine regions, but this species is exceptionally beautiful when in health. The ovate leaves are thickly covered with long silky white hairs, which, contrasted with the pinkish flowers, render the plant very pretty. The branches are trailing, growing very freely, producing numerous umbels of flowers of a deep blush colour. The umbels are about 1½ inch across, thickly set with flowers, which last a considerable time, and they are produced from April to August; in fact, we have seen them after that time during the past season. The plant enjoys a well-drained and warm position on the rockery, and in the event of a very wet winter it is best to cover something over it, as the woolly leaves are apt to suffer. The long shoots look exceedingly pretty over a ledge on the rockwork.

Oyananthus lobatus.—This is one of the numerous alpine plants from the Himalayas. It has a large perennial fleshy rootstock, from which are annually produced numerous trailing branches with small rather dentated or lobed leaves, while the flowers are produced at the extremities of the shoots. The flowers are about 1 to 1½ inch across, clear sky-blue colour, with the throat white with silky hairs. This also requires a warm and well-drained position on the rockwork, and as far as our experience goes it does not require any protection whatever, but has stood very severe winters with us (South London). It delights in a rich soil.

Viola gracilis.—Taking the Violas as a whole, they form a handsome family, we mean regardless of the progenies of cornuta, tricolor, &c. This species, however, we consider one of the best. It is a very free grower, most profuse bloomer, and with good habit, which is suitable for the rockery or border. The flowers are about an inch or more in length, deep bluish purple, produced in enormous quantities all the summer, and when the erect flowers are seen covering the dark green shoots

trailing over the rockery it must be considered one of its best ornaments.-T.

REVIEW OF BOOK.

Rays from the Realms of Nature, or Parables of Plant Life, By the Rev. James Niel, M.A. London: Cassell, Petter, and Galpin.

THE author of this work has successfully endeavoured, in describing some well-known or remarkable plants, to deduce from a study of vegetable life illustrations of scriptural truths. The high moral tone and pleasant instructive style of the writer render the book an excellent one for presenting to young people, and indeed there is much that could be read with advantage by those more advanced in years. For this reason we recommend it to parents who are desirous of placing in the hands of their children works of unquestionable morality.

The following passages will sufficiently indicate the general character of the book. In the chapter aptly entitled "Death unto Life" we find this graphic description of the origin and

progress of vegetation on islands-" Observe the life if tary islands. At their birth they were bare rocks. Then the loans came and fixed its slender film, bloomed, and wither a left behind the first faintest indication of soil. Next are Moss, raising its slender stalk, soon to pass away and and and tiny deposit of earth. Now the hardy Fern at peared. are a up again and again in wild profusion in its turn to replenish the ground. In time the very rock aseif, un by the influences of sun and shower, decayed and crumbled says. and rolled down in its run rich fertile metid. The washed upon its shores cocoa nuts, which during last weet storms they had spatched from some far-off beachtravellers whose fragile bark is so wonderfully possed as to float in salt water and sink when it reaches fre-h. dropped over it in all directions the seeds which formed the often undigested food. Then came many a wild flower and many a stately tree. Centuries pass by, and out of this centery of nature comes a glorious scene of life."

Under the same heading are some references to the woods.

"When the secrets of the m ne are revealed of geology.

Fig 50. A POREST IN THE COAL PERIOD.

see how its black veins consist of the buried ruins of vast forests and ferneries of tupendous growth and rank .uxurance. Singularly grand and beautiful were the lonely groves The markings or regular tracery on the of that primal era. stems of the plants led Hugh Miller to style this vegetation the sculpturesque. He says, 'In walking among the ruins He says, 'In walking among the ruins of this ancient flora the palesontologist almost feels as if he had got among the broken fragments of Italian Lalaces erected long ages ago, when the architecture of Rome was most ornate and every moulding was roughened with ornament; and, in attempting to can up in fancy the oli carboniferous forests, he has to dwell on this peculiar feature as one of the most prominent, and to see, in the multitude of tranks darkened above by clouds of foliage that rise upon him in the prospect, the alim columns of an elder Albambra roughened with arabesque tracery and exquisite filagree work. These age after age alternately filurished and fell, and were finally overwhelmed in periods mimensely remote; yet their destruction has given to man the coal which forms the very sinews of the wondrous life of commerce and arts in these last days."

The annexed engraving (fig. 60), for which we are indebted

to Messrs. Cassell, Petter, & Galpin, will convey a good idea of the illustrations with which the book is freely adorned, and also enable our non-grological readers to form some conception of the peculiarities of plant life in the coal period. On the right and left of the engraving are trunks of Bigillarias, Lepidodendrons, and Tree Ferns, while in the background are seen gigantic allies of the Lycopodiums (Lycopodius), Calamites, &c. We may remark that in the coal measures of Great Britain over three hundred fossil species of plants are found, the

majority of which are very distinct from existing forms.

A description of the Valisheria spiralis is correct, but the writer has omitted the fact that the staminate flowers are produced near the root, and when mature separate from the plant and rise to the surface of the water, there floating about

and fertilising the pistillate flowers.

The frontispiece is a coloured floral dial, but the times fixed for the opening and closing of the flowers must only be taken as approximately correct. The information conveyed is generally accurate and reliable, but a few errors occur of which we especially remarked the following. The Agave americana is stated on page 88 to be included in the same family as the Pine Apple, whereas the former is a member of the Amaryllidscene and the latter of Bromeliacese. Cocus should be Cocos. Urania speciosa is not a Palm but allied to the Musas, and Papaver Algemone appears for P. Argemone. It is scarcely necessary to add that the type, paper, binding, &c., are all that can be desired in a work of this kind.

GOOD PEARS .- No. 2.

FOLLOWING closely on the varieties referred to last week, indeed not infrequently ripening contemporaneously with some of them, are many Pears of recognised value. As a worthy

example of September Pears we figure this week the fine, tree-growing, good-bearing, and excellent Pear Beurré d'Amanlis. Our experience of this variety is, that it is one of the hardiest and most reliable Pears of its season. It will thrive over a very wide district of the country, whether grown on the Pear on Quince stock; but on the latter the fruit is occasionally gritty when the trees are grown in shallow soils in dry localities. It makes a fine espalier on the Pear, and a handsoms pyramid on the Quince; in fact, so generally satisfactory do we find Beurré d'Amanlis, that perhape the most useful information that can be afforded respecting it is for cultivators to state where and under what conditions it does not succeed, and

Fig. 51.—BRURRE D'AMANLIS.

whether it has proved serviceable as standards for orchards. Before, however, information is submitted in reference to this Pear it will be well to wait until a few other varieties ripening about the same period are submitted, so that the September Pears can be considered in a group the same as the earlier varieties mentioned last week. We recommend this course as the most convenient for all. Beurré d'Amanlis has been stated to be a seedling of Van Mons, but as is stated in the "Fruit Manual," it is probable that it is a native of Brittany.

We have received some valuable communications on Pears, but only a few of the writers have confined their remarks to the early section, having referred also to late varieties; therefore only a portion of the communications can be inserted at

THE CHEMISTRY OF GARDEN CROPS.

To the gardener the chemistry of crops is a matter of great importance, because he cannot restrict his operations to such crops as the land is particularly adapted for, but must endeayour to render his land capable of carrying more or less of all

the vegetables and fruits that find a place in the catalogue of domestic wants. Plants consist of two classes of constituents—the Inorganic, which may be called the foundation; and the Organic, which may be considered the superstructure. The first alone concerns us now. A plant must derive from the soil certain proportions of silica, lime, sulphur, salt, phosphates, alkalies, and other minerals, or it cannot exist at all; but given these, and its production of fibre, starch, gum, sugar, and other organic principles, will depend very much upon the action of light, heat, atmospheric air, and moisture upon it, for these have to be produced by chemical (or vital) action within the structure, or, as we sometimes say, the tissues of the plant itself. To a very great extent the agencies that conduce to the production of organic principles are beyond our control (though not entirely so), whereas we can directly, and to a very considerable extent, provide the plant with the minerals it more particularly requires; first, by choosing the ground for it and next by tilling and manuring in a suitable manner.

it more particularly requires; first, by choosing the ground for it, and next by tilling and manuring in a suitable manner.

Garden soils usually consist of loam of some kind, the consequence of long cultivation. Natural loams are the result of the decay and admixture of various earths, and they are

mostly of a mellow texture, easily worked and highly produc-They are, as a rule, the best of all soils, and their good ness is in great part due to the fact that they contain a little of everything, with no great predominance of any one particular earth. Cultivation also produces loam. On a clay land we find a top crust of clayey loam, and on a lime or chalk land a top crust of calcareous loam, where cultivation has been long pursued, for the staple is broken and manures are put on, and the roots of plants assist in disintegrating and decomposing. and thus there is accumulation of humus and a decomposition of the rock proceeding together, and a loam of some sort is the result. Hence the necessity of caution in respect of deep trenching, for if we bury the top soil and put in its place a crude material that has not before seen daylight we may lose ten years in profitable cropping, because we must now begin to tame a savage soil that we have been at great pairs to bring up to cover a stratum of a good material prepared for us by the combined operations of Nature and Art during perhaps several centuries. But deep and good garden soils may be safely trenched and freely knocked about, because not only does the process favour the deep rooting of the plants, but it favours also that disintegration which is one of the causes of fertility. Every pebble is capable of imparting to the soil a solution—infinitesimal perhaps, but not the less real—of silica, or lime, or potash, or phosphates, or perhaps of all these; but it must be exposed to light and air and moisture to enable it to part with a portion of its substance, and thus it is that mechanical tillage is of the first importance in all agricultural and horticultural operations.

The principal inorganic or mineral constituents of plants are potash, soda, lime, sulphur, salt, silica, and phosphates of lime and iron. Clays and loams are generally rich in potash, sul-phur, salt, and phosphates, but deficient in silica and lime. Limestone and chalk are usually rich in lime and phosphates, but deficient of humus, silica, sulphur, salt, and alkalies. Sandy soils are rich in silica, and are rarely deficient of lime, but are generally poor in respect of phosphates and alkalies. Therefore, in manuring a clay or loam, farmyard dung is invaluable because of the silica it contains, as well as for other ingredients that all crops appreciate. The occasional application of lime also is of importance, and not seldom this produces an almost magical effect on an old garden soil that has been heavily cropped and liberally manured. Calcareous soils are also greatly benefited by a free application to them of manure from the stable and cow-byre; but it would be, generally speaking, like carrying coals to Newcastle to dress these soils with lime. But clay may be put on with advantage; and nothing benefits a hot chalky soil more than a good dose of old mud from ponds and ditches, supplying at once humus, alumina, and silicates. In the manuring of sandy soils great care is requisite, because of their absorbing power. In the bulbgrowing districts of Holland cow dung is worth the enormous price of 1s. per barrow-load, for digging into loose sand for a crop of Potatoes, to be followed by bulbs. This is an exceptional case, but it illustrates the subject usefully. As a rule, sandy soils are deficient of phosphates and alkalies, and hence, instead of employing dung, which may often be more usefully bestowed upon the loamy pieces and reserved for special purposes, it will be found that kainit (a rough form of potash) and superphosphate of lime will conjointly produce the best results, more especially in raising Potatoes, Onions, and Carrots, which are particularly well adapted for sandy soils. Probably the best universal manure is genuine Peruvain guano, for it contains phosphates, alkalies, and silicates in available forms and suitable proportions. In any case, however, a manure should be selected by analysis, and with a view both to correct the deficiencies of the soil and satisfy the requirements of the crops to be grown on it.

For the present purpose the principal garden crops may be grouped in two classes, in accordance with the predominance of certain of their mineral constituents. The figures show the average proportions of the several minerals per cent. in the ashes that are left after burning a sample.

In Class 1 phosphates and potash predominate. This class includes the following:—The Pea, containing phosphates, 33; potash, 36. The Bean: phosphates, 31; potash, 42. The Potato: phosphates, 12; potash, 53; lime, 2; magnesia 5½ to 7 or 8. The Parsnip: phosphates, 18; potash, 36; lime, 11; salt, 5. The Carrot: phosphates, 8; potash, 32; soda, 13; sulphuric acid, 6; salt, 6. The Jerusalem Artichoke: phosphates, 13; potash, 54.

In Class 2 sulphur, soda, and salt predominate. This class

includes the following:—The Cabbage: phosphates, 12; potash, 11; soda, 20; lime, 20; sulphuric acid, 21. The Turnip; phosphates, 9; potash, 28; salt, 16; lime, 23; sulphuric acid, 12. The Beet: phosphates, 4; potash, 23; soda, 19; salt, 24; lime, 1.

As a matter of course, Lentils and other kind of pulse agree more or less with Peas and Beans in the predominance of phosphates and potash. So, again, all the Brassicas, whether Kales, Cauliflowers, or whatever else, agree nearly with the Cabbage in a predominance of lime and sulphur, ingredients which fully account for the offensive odour of these vegetables when in a state of decay. Fruits are mostly highly charged with alkalies, and are rarely deficient in phosphates; moreover, stone fruits require lime, for they have to make bones as well as flesh when they produce a crop. As regards the alkalies, plants appear capable of substituting soda for potash under some circumstances, but it would not be prudent for the cultivator to assume that the cheaper alkali might take the place of the more costly one as a manurial agent, for Nature is stem and constant in her ways, and it can hardly be supposed that a plant in which potash normally predominates can attain to perfection in a soil deficient in potash, however well supplied it may be with soda. The cheaper alkali in combination with salt may, however, be usefully employed in aid of quickgrowing green crops; and more or less with tap-roots and Brassicas. As regards Potatoes, it seems worthy of observation that they contain but a trace of silica, and yet they usually thrive on sand, and in many instances crops grown on sand are free from disease and of high quality, although the dead weight may not be great. The mechanical texture of the soil has much to do with this; and when that is aided by a supply of potash and phosphates, whether from farmyard dung or artificials, sandy soils become highly productive of Potatoes of the very finest quality. On the other hand, Potatoes also grow well on limestone and chalk, and yet there is but little lime in them. Here, again mechanical texture explains the case in part, and it is further explained by the sufficiency of potah and phosphates, as also of magnesia, which enters in a special manner into the mineral constitution of this root.

Thus far we have not even mentioned nitrogen, or its common form of carbonate of ammonia; nor have we mentioned carbon, nor its very familiar form of carbonic acid. These are important elements of plant-growth. By the aid of nitrogenous "principles. By the aid of carbon it secretes vascular tissue, starch, and other "carbonaceous" principles. Both these aids to plant life are required in the soil, and hence one reason of the efficacy of manures derived directly from the animal kingdom, as, for example, the dung of animals, including guano, which consists, in part at least, of the droppings of sea birds. The nitrogen in these substances, however, is of an evanescent character, and rapidly flies away in the form of carbonate of ammonia; hence a heap of farmyard dung left for several years becomes almost valueless as manure, and guano should be kept in bulk as long as possible, and protected from the atmosphere, or its ammonia will disappear rapidly. One reason for the activity of chemists and others in the preparation of artificial manures is the difficulty of "fixing" the needful ammonia so that it may be kept from combining with the atmosphere, and at the same time be always in a state in which it can be appropriated by the plant. We cannot supply plants with nitrogen directly, but in all good manures there is a certain proportion of it in combination, and in many instances the per-centage of nitrogen is made the test of the value of a manure. The importance of humus in a soil is that by its decay it supplies the plant with carbonic acid, of which it consumes enormous quantities. Thus manures that are valueless by the nitrogen test may still be valuable as generators of carbonic acid. Vegetable refuse of all kinds, whether leaves, spoilt hay, sawdust, coos-nut fibre, &c., may be regarded as possible elaborators of carbonic acid, and therefore of great service when dug into the soil. But we obtain useful herbage, at all events, if we do not obtain come and wine and oil few lends that the come and wine and oil few lends that the come and wine and oil few lends that the come and wine and oil few lends that the come and the service when the come and the come a corn and wine and oil, from lands that appear almost destitute of nitrogenous substances and humus. We therefore conclude that the useful herbage and the whole of the vegetation on these lands depend for their nitrogen and carbon on the atmosphere. But when we take such lands into cultivation, the herbage it naturally produces does not suffice us, and we break up the staple that decomposition may liberate more abundant supplies of plant food, and we put on such fertilising agents as are best adapted to rectify the natural deficiencies of the

soil, so far as the means at our command enable us to meet the requirements of the case as indicated by chamical considerations.—(Abridged from Sutton's Anatours' Guide.)

JUDGING COLLECTIONS OF FRUIT.

On page 331 of the Journal of October 23rd Mr. Witherspoon submitted for consideration a system of judging by points the competing collections of fruit at public exhibitions. As yet I have not observed that any of our well-known fruit exhibitors or fruit judges have expressed an opinion on the merits of the plan indicated by Mr. Witherspoon. My own opinion is, that the system is worthy of consideration. If carried out exhibitors would have the satisfaction of knowing the grounds on which the judges arrived at their decision as regards the respective merits of the competing collections. I should like to hear through your columns what others interested in fruit-exhibiting have to say for or against the plan of judging as suggested by your correspondent.—EXHIBITOR.

BRITISH FERNS .- No. 2.

CONTINUING the subject from last week, I now refer to the

remaining British genera.

Lastreas are rather numerous, for there are eight distinct species. L. semula, or Hay-scented Buckler Fern, is a beautiful plant and the best suited for pot culture. I have two plants in my collection—one from Ireland, the other collected near this town, and is much better than the Irish one, being closer and more compact in its habit. L. cristata, or Broad Buckler Fern, is a bold-fronded plant. The name was given to it by Linnseus from a fancied resemblance to the crest of the peacock in the way it produces its fronds. Spinulose and uliginose are considered to be varieties of the above by some, but I doubt it.

L. dilatata has several good varieties. Grandiceps is the finest created variety that I have ever seen, and was raised by Mr. Barnes of Levens. He has another type raised at the same time; it is also crested, but differs from the above. I have also one from Mr. Clapham, which he kindly gave me when I visited his fernery last year, and a beautiful plant it is. Mr. Clapham named it grandens. Cristata gracilis is another good variety, and much like the last-named. The next species is the Lastrea Filix-mas, a plant that most are acquainted with that know anything about Ferns, and many of its varieties are worthy of places in every fernery. L. F.-mas cristata, which by some is styled the "King of Male Ferna," was collected in Cornwall, and no doubt will hold its place as a first-class plant, although it is now in every large fernery in the kingdom. L. F.-mas cristata angustata, a seedling raised from the above, is very good. L.F.-mas var. crisps is much admired and quite unique, differing from the common type in the widest manner imaginable. The fronds are 9 or 10 inches in length and very much imbricated, giving to the plant a compact and exceedingly pretty appearance. It is from Wales, and was sent out by Mr. Appleby of Balby near Doncaster. There is also a crested variety raised from the above, which is very good and worthy of notice. Crispatissima is another fine variety, and was raised by Mr. T. Bolton of Warton near Carnforth. Its crispy appearance and shuttlecock habit of growth combine to make it an object of great beauty. The variety grandiceps is said to be the finest crested form of the true L. F.-mas ever found, and it is without doubt a grand variety. Ramo-cristata is also a fine plant, and was raised by the above Mr. Bolton. L. Oreopteris, or montana, is to be found in abundance about Bell Hagg and Rivelin. The varieties of this Fern are few, and the best I have seen are in the possession of Mr. Barnes of Leven, and have been found in the Lake district. The first I will refer to is unique, and was named Barnesii by Mr. Moore. It is a beautiful plant of upright growth. In the same collection are several very good crested varieties.

Ophioglossum vulgatum, or Common Adder's-tongue.—There

is one variety of this plant named lusitanicum.

Osmunda regalis, or Royal Fern.—I found several plants of this noble Fern some years ago near Ashopton in Derbyshire, and have one of them in my possession which has produced this season fronds over 5 feet in length. This plant also grows near Sheffield, but there are few plants to be found now in these parts. There are several varieties, but I shall only refer to one—cristata, a very handsome plant. I think it almost impossible for any person to see a superior specimen without being smitten by its beauty.

Polypodiums.—There are five distinct species in this class.

The first four are not given to sport, so as to produce any varieties of note. P. alpestre, or Alpine Polypody; P. Dryopteris, the much-admired Oak Fern; P. Phegopteris, or Beech Fern; and P. Robertianum, or calcareum, are the four. I leave these to speak of the P. vulgare and its numerous varieties, which are very beautiful. Most, if not all, are acquainted with P. cambricum, and cannot fail to admire it; but this fine variety has now many rivals. P. elegantismum was found in Cornwall, and first sent out by Messrs. Stansfield & Son. It is exquisitely delicate, and much resembles the beautiful Killarney Fern. It is by far the most attractive of all the varieties. The next in order is P. Prestonii, which was collected by Mr. Preston in Silver Dale, and is a splendid variety of the Cambricum type.

Polystichums.—In this genus there are three distinct species. The first (aculeatum, or Prickly Shield Fern) is of a rich glossy green and of a good habit, and some of the varieties are very good. The following are a few of the best:—Acrocladon, a splendid form of the grandiceps type; cristate gracile is very good; and proliferum is also very good, and finely divided. The well-known P. angulare is a fine plant, and has produced many beautiful forms. The following are a few of the best:—Cranfordianum Footii, Henleyii, lineare, proliferum, tenue, Wollastoni, and lastly Brearlii (the original plant of this variety is in my own collection). There are also many fine crested varieties, and also the handsome variety plumosum and Pateyi, two plants of great merit and beauty. The third plant in this class is P. Lonchitis, a fine plant when well grown, which is not often the case.

Pteris aguitima, or Common Brake. Some readers will expect to hear but little of this. There are, however, several varieties of great merit. I saw some of these at Mr. Barnes's last year which surprised me; and semi-crested plants of great beauty, which he had collected on the hills and established in

his own grounds.

Scolopendrium sulgare is the only species in the British Isles, but the varieties are very numerous indeed. These amount to about five hundred, and, as Mr. Stansfield remarks when speaking of this Fern, "it is the most remarkable of all Ferns, its named varieties are now counted by hundreds." I will now refer to a few of the best I am acquainted with. S. Coolingii is the best crested variety I remember to have seen; the true plant is a gem. S. crispum is a good old variety. Next we have the crested and crenate varieties of crispum. Then we have coronatum, a new variety, of good habit and great merit. S. ramo-digitatum is a very fine form, much branched and crested. It was found by Mr. T. Bolton of Warton on Warton Crag.

Trichomanes radioans, or Irish Bristle Fern, is one of the most attractive of our native Ferns, and its fronds will after they are fully developed continue fresh and beautiful much longer than those of any other species. The varieties of this lovely Fern are few but very good. T. Andrewsii is a plant of great beauty, and deserves a place in every collection. Dilatatum and dissectum are also good. There is, too, a Welah plant of this class which is considered by some to be better than the Irish species.

Woodrias.—The species alpina and Woodsia ilvensis are only to be found in the north, and when found are rather shy in cultivation and of no special interest to the Fern cultivator.

-JNO. EADON, Sheffield.

BRANCEPETH CASTLE,

THE SEAT OF VISCOUNT BOYNE.

THE magnificent cathedral and castle of Durham standing out so prominently to the view of the spectator are objects which at once inspire the impression that he is near a city of importance: indeed, one richer in historical lore is not to be found in Great Britain, and no visitor to the north should

miss an opportunity of seeing it.

Among the many old castles of the county there is none older than Brancepeth. In olden days it was a well-known custom that when a castle was to be built a license was granted for the purpose; but in none of the old archives can such be found relating to Brancepeth, which proves beyond doubt the antiquity of the building, belonging as it did to the Nevilles, a family renowned for their valour—in fact, as noted as the Percys of Northumberland, with whom they were contemporary. The Nevilles are stated to have come over with the Conqueror. Geoffrey de Neville, who married the heiress of Bertram Bulmer and inherited these estates, which the ancient

family of Bulmer retained a long time. The Castle is a very fine building. Leland describes it as "strongly set and builded, and hath two courts of high building. In this court be three towers of lodgging, and three smalle adorn-ments." Hutchinson describes it: "Within the wall are a spacious area, which you enter from the north by a gate with a portcullis, and defended by two square towers." The north and east sides have been defended by a moat. The west and south sides are built on a rock 40 feet high, with a brook at the foot. The interior of the Castle is quite princely. barons' great hall contains the suit of armour won by King David at the battle of Neville's Cross; and at the end of this apartment is a rich stained window, which contains three distinct views of the noted battle of Neville's Cross. There is also a very large corridor, which is full of coats of mail and armour. The whole place is well furnished and in unison with the rest of the Castle.

About a century ago it was purchased by Mr. Russel, who pulled part of it down and had it rebuilt in the same style of imposing architecture. There is also a very fine church which the public have the use of; it is very ancient too, and contains the ashes of many members of the Neville family. So old is it that at the east end still remains the small belfry for ringing the angelus. The name of Brancepeth springs from "The Brawn's Path," as in those days it was supposed to be the walk of a very fierce one, which was destroyed by one of its lords, hence its name. The seventh Viscount Boyne, the descendant of the house of Hamilton in Scotland, married the daughter and sole heiress of Matthew Russel, Esq., M.P., of Brancepeth, and at the latter's death in 1850, on attaining the estates, he assumed the surname and arms, and the present

nobleman is his son and the eighth viscount.

The flower garden is near to the west side of the Castle, and was formed about 1854 by Mr. Dale, the gardener. a Rose garden and also a very neat Box garden, in which the monogram "E. M. B." of the late Counters Emma Maria Boyne is artistically cut out in Box, also is embedded the Shamrock, the Rose, and the Thistle. The beds in the flower garden were very neatly filled with well-selected flowers. We observed some fine beds filled with Dickson's yellow Viola, Ageratum Cupid—a very fine colour, lately sent out by Messrs. Downie and Laird—Flower of Spring Pelargonium, Pyrethrum, and Viola Perfection. Overlooking the dell or glade into the brook is a Rose terrace, which enhances considerably the surroundings. This glade was all laid out by Mr. Dale too, and must have been a work of uncommon difficulty owing to the steep and rugged ascent. The bank is planted with fine clumps of Rhododendrons. We also observed a beautiful Spanish Chestnut and good specimens of Wellingtonia gigantea; but forest trees and shrubs do not flourish well, owing to the smoky nature of the neighbourhood, which is entirely surrounded by collieries.

A walk of a quarter of a mile or so brings you from the Castle to the kitchen gardens, which are over 41 acres, and are divided into two divisions by a wall. A large part of it has been reclaimed from a bog at considerable expense and trouble. We were shown Peas sown in March which were still bearing at the time of our visit—the end of September. Brussels Sprouts were also good in comparison with what they are in many places in the north this year. Broccoli was also healthy, and seemed well prepared to withstand the winter, Messrs. Veitch's Autumn Protecting being here an indispensable favourite for early work. Asparagus we observed was grown in narrow beds of 3 feet and well raised up. By this method good Asparagus is procured, which could not be ob-tained by the usual method, owing to the boggy and wet nature of the soil. Pears and Apples were not a heavy crop. Amongst Pears as standards Muirfowls Egg was a very good

crop, and does well at Brancepeth.

In the inner division of the kitchen garden is situated the glass houses, and in the centre of the range is the conservatory. From here runs a walk 8 feet broad, which divides this portion of the garden equally, and the border on each side was bedded out effectively with ribbon borders of Kaiser William Lobelia, Cloth of Gold and Violet Hill Pelargoniums, Pyrethrum, and Perilla nankinensis, and in the background at equal distances were planted Irish Yews, which gave a finished effect; and in the centre of the walk was an octagon fountain, where another walk joins at right angles. The conservatory was designed by Mr. Weeks of London, and is 43 by 30, with a little glass portico for the entrance. Amongst the climbers trained against the wall we noticed an old favourite—Swainsonia galegifolia, with its charming Pea flowers so profusely scattered all over!

the plant. How seldom this plant is seen! and what can be finer for a greenhouse, flowering at all times so profusely, and of such easy culture? also Clematises, Lapageria roses, and L. alba gracefully intertwining in each other. There was also a very fine specimen of Phormium tenax variegata, and the usual decorative plants.

From here you enter the early and late Peach houses on your left, 36 by 21 respectively. In the late house were Pine Apple Nectarine, Early Savoy and Princess of Wales Peaches; and the early house contained Newington Nectarine, Bellegarde and Royal George Peaches. The trees all looked very healthy, and had made excellent growth. Returning through the conservatory again we were shown into late vineries 80 by 28 feet, and containing Barbarossa, Muscat of Alexandria, Ms. Pince, Raisin de Calabria, Alicante, and Golden Queen. The bunches were very evenly distributed over the house, and of good table size. There was a large lean-to stove filled principally with decorative plants, Orchids, &c.; another vinery for early work and a lean-to greenhouse completed this range. Outside of this house we were shown a Jargonelle Pear planted by Mr. Dale's father at the time he made these gardens in the ear 1820. It is also worthy of record here that Mr. Dale and his respected sire have been in the service of the Brancepeth family for over eighty-nine years. Near to Mr. Dale's house are the Pine pits, the successional house being 43 by 21 feet, and in one end of the plunging bed were planted out specimens of Eucharis amazonica, and they were bearing a nummens of Eucharis amazonica, and they were bearing a number of spikes. The successional Pines were all very fine and healthy. The fruiting house is 60 by 24 feet, span-roofed, with a side stage, in which some excellent plants of Calanthe vestita were looking extremely well. There has been a remarkable freak of Pine growth here which is worthy of record, as many as six small fruits being thrown up in some instances—and all about the size of a goose egg—ripening and swelling their pips well. No particular reason can be given for this; it has only occurred within this last year or so. Mr. Dale thinks that it is owing to the polluted state of the neighbourhood with smoke of all kinds, some chemical or alkali deposit has been placed in the turf which they were potted in. Mr. Dale has had the top thinly pared. The plants have all been now repotted in the new pared turf, and seem to have completely recovered. Pine Apple culture has always been one of the great features at Brancepeth, and all the leading varieties are grown.

The gardener's house is worthy of mention from the fact that the entrance room is entirely devoted to a collection of stuffed birds, animals, serpents, fishes, and cabinets full of the rarest kinds of eggs; in fact a veritable little museum, all the specimens having been gathered and preserved by Mr. Dale himself, the result of a life-long labour. We also saw a handsome volume of Mr. Waterton's work, which had been presented to Mr. Dale by that distinguished author and naturalist in recognition of his services in the above sciences.—B. COWAN.

SAXIFRAGA FORTUNEI.

I HAVE proved this Saxifrage to be a useful autumn and early winter-flowering plant for the greenhouse and conservatory, but I had no full conception of its merits as a decorative plant until recently. In a large conservatory I saw this Saxifrage arranged in large numbers. The plants were in 7-inch pots, and were bearing fine bright foliage and sturdy flower stems about 18 inches high, displaying their pretty white flowers in profusion. It is readily increased by division, and appears to form seed pods freely, but I have not yet tried to increase it by seed. The spring and summer is the best time for propagation. The pots should be thoroughly drained, employing a compost consisting of sandy loam, peat, and leaf soil in equal quantities, a little charcoal dust, and coarse sand. Care must be exercised in watering the plants until they begin to make free growth, then they will require it more liberally. I find them succeed during the summer placed in a partially shaded situation on a firm bottom of ashes.—SAXUM.

AMERICAN CANNED GOODS.—The trade in this is of great magnitude. We learn that from four to five millions of cans of Peaches, Tomatoes and corn, from eight to ten millions of cans of fruit, and from six to ten millions of cans of vegetables, are packed annually in the City of Baltimore alone. Pickles, sauces and preserves are also canned there and sent to all parts of the world; the Hindoos,

Japanese and Chinese, as well as Europeans, being among the customers. A leading dealer states that the trade in canned goods is ten times larger than it was four years ago, and that this has been occasioned by the addition of new articles, in both the fruit and vegetable lines, to the business. A single Broad Street firm sold last year six hundred thousand scaled cans of Tomatoes alone, besides shiploads of Boston baked Beans, Peas, corn, &c., not counting the goods usually scaled in glass jars and bottles under the head of catsups, sauces and preserves.

FOLK-LORE OF THE HOLLY AND MISTLETOE.

One of the most popular plants at this season is the Holly, which, with its dark shiny leaves and bright red berries, is much in request for dressing up our churches and houses at Christmas. On this account one of its popular names is "Christmas." The term Holly is in all probability a corruption of holy, as this plant has been used from time immemorial as a charm against evil influences. Hence it was hung round or planted near houses as a protection against lightning. Its common use at Christmas is, says Mr. Napier in his "Folklore of the West of Scotland" (1819, p. 121), "apparently the survival of an ancient Roman custom occurring during the festival to Saturn, to which god the Holly was dedicated. While the Romans were holding their feasts, which occurred about the time of the winter solstice, they decked the outsides of their houses with Holly. At the same time the Christians were quietly celebrating the birth of Christ, and to avoid detection they outwardly followed the custom of their heathen detection they outwardly followed the custom of neighbours and decked their houses with Holly. In this way the Holly came to be connected with holy also." It is curious that Shakespeare only once mentions the Holly, and then in "As You Like It" (Act ii., Sc. 7). Holly is used in some districts for divination. Thus in Northumberland we bear of a he-Holly and a she-Holly, according as it is with or without prickles, the leaves of the she-Holly being alone deemed proper for divination. These must be plucked late on a Friday night by persons careful to preserve an unbroken silence from the time they go out to the next morning's dawn. The leaves must be collected in a three-cornered handkerchief, and on being brought home nine of them must be selected, tied with knots into the handkerchief, and placed beneath the pillow. Dreams worthy of all credit will attend this rite, and no small importance is consequently attached to them, as they are supposed, in the most unerring manner, to predict future events. The Holly on account of its prickly leaves is much used for hedges. John Evelyn, in his Diary, alluding to this plant, asks, "Is there under heaven a more glorious and refreshing sight of the kind than such an impregnable hedge, glittering with its armed and varnished leaves, the taller standards at orderly distances blushing with their natural coral?" Evelyn had such a hedge at Say's Court, 400 feet long, 9 feet high, and 5 feet broad, which he planted the proposition of the planted of the proposition of the planted of the proposition of the planted o at the suggestion of Peter the Great, who resided at his house while he worked in the Deptford Dockyard.

The Mistletoe from the earliest times has been an object of interest to naturalists on account of its curious growth, deriving its subsistence entirely from the branch to which it annexes itself. Thus Herrick describes it as—

"The mystic Mistletce,
Which has no root and cannot grow
Or prosper but by that same tree
It clings about."

The Greeks and Romans both knew of this plant, and the Druids held it in the greatest veneration. The ceremony of gathering it at the commencement of the year was performed with every kind of pomp. The Druid priests, we are informed, went in solemn procession into the forests, where they raised a grass altar at the foot of the finest Oak on which the Mistletoe was found growing, and inscribed on the trunk of the tree the names of the most powerful among their deities. The Chief Druid, clad in white robes, then ascended the tree, bearing a consecrated golden pruning-hook, with which he cropped the Mistletoe, and dropped it into a "white sagum," or pure white cloth of wool, held out beneath the tree by the remaining priests. Should any part of the plant accidentally touch the ground, it was considered to be an omen of some dire misfortune about to visit the land. This ceremony was celebrated on the sixth day of the moon, and when it was concluded a sacrifice was made of two white bulls. Our practice of decorating houses at Christmas with Mistletoe is

probably a remnant of this superstitious custom. Brand thinks that this plant was never put up in churches except by mistake or ignorance of the sextons, "it being a heathenish and profane plant, distinguished in pagan rites." It is certain, however, that during the feudal ages the Mistletoe was gathered with much solemnity on Christmas eve, and hung up in the great hall with loud shouts of rejoicing. In many country places the entire plant is still hung up in the kitchens of farmhouses, &c. Various superstitious notions are still attached to it, which too are not confined to our own country. Shakespeare alludes to it in his "Titus Andronicus" (Act ii., Sc. 3), and calls it the "baleful Mistletoe," and Gay styles it the "sacred Mistletoe." In Halstein the Mistletoe is the "märentaken," or "branch of spectres," and is supposed to confer upon its possessor the power of seeing ghosts. No allusion to kissing under the Mistletoe is met with earlier than the middle of the seventeenth century.—(Rev. T. Thiselton Dyee, M.A., in "Leisure Hour.")

WORK! FOR THE WEEK.

HARDY FRUIT GARDEN.

When the weather is open the planting of fruit trees should be proceeded with. Proceed also with the pruning if necessary of such trees against walls as the Cherry, Plum, and Pear, also the Apricot, Peach and Nectarine, but in the case of the Peach and Nectarine pruning would be preferably deferred until spring. Whenever the condition of fruit trees appears in any respect unsatisfactory the roots should be carefully examined. In cases of exhaustion remove the surface soil carefully examined. In cases of exhaustion remove the surface soil carefully so as to expose a considerable portion of the roots, especially near the stem, carefully avoiding injuring them, and then cut away all dead or decayed roots. Employ for filling-in a compost of two parts of good turfy loam well chopped up and a third of thoroughly decomposed manure, and if the soil be deficient in calcareous matter a tenth part of old mortar rubbish may be added with advantage, working the fresh compost in amongst the roots, covering them 3 or 4 inches deep, and mulching the surface with short stable litter. Excessive luxuriance in fruit trees can generally be remedied by judicious root-pruning. Standard trees should receive attention, removing all superfluous shoots or branches, especially where much crowded and those crossing each other, but avoid pruning too severely, as that will only tend to an increase of growth. Locality and the nature of the soil have greatly affected the quantity and quality of the fruit, and where the soil and climatic conditions are most favourable the least aid will be required, but in most instances timely attention will be necessary to prevent entangled growth. Old trees that are becoming unproductive, or where the variety is of inferior quality, or from being affected by canker is unsuitable to the climate and soil, may be headed back and grafted in March with varieties that have been proved to be well suited to the locality. Improved or new varieties should be tried on a small scale prior to extensive planting. Were thi

FRUIT HOUSES.

Pines.—In most establishments where Pine Apples are grown there is a demand for ripe fruit in May and June, and it will be necessary to take into consideration the present condition of the plants that are intended to afford that supply. Where a sufficient number of Smooth-leaved Cayenne, Charlotte Rothschild, Black Jamaica, Black Prince, with Montserrat failed to show fruit during October and November, and as the fruits starting now will not be ripe at the requisite time, plants of the Queen, Providence, and Enville varieties, which require less time to arrive at perfection, should be induced to start their fruit. Select from the successional stock plants that have been subjected to somewhat cool and dry treatment, choosing those which have an enlarged base with a tendency to open at the centre. Place them in a light house or pit, and plunge them in a brisk bottom heat of 85° to 90°, the atmospheric heat ranging between 60° and 70° at night according to external conditions, allowing from 5° to 10° more by day. A genial atmospheric moisture must be kept about the plants, but not by steaming intensely from hot-water pipes or syringing the bed between the plants, but by occasionally damping cool surfaces about the house. The soil must be examined once a week, employing tepid water with a little guano in it, applying it copiously when needed.

Cucumbers.—The weather of the past few weeks has necessitated sharp firing, and one consequence is weak and attenuated growth.

Light is very important in the cultivation of the Cucumber in winter, and now the days are so short keep the glass as clean as possible both inside and out. Do not supply strong liquid manure too freely, as it is the reverse of good treatment to stimulate them unduly at any time. The soil, however, applied to the roots should be rich and sweet. Be careful not to overcrop the plants, and do not allow the fruits to hang too long; they keep fresh several days after being cut if the heels are inserted in saucers of water in moderate heat. Remove superfluous fruits as they appear, and tie the growths as necessary. Bed spider is sure to appear during a period of sharp firing. Sponging with a weak solution of soft soap, 2 ozs. to the gallon, is the safest remedy; and if mildew appear dust the affected parts with flowers of sulphur, and reduce the atmospheric moisture. Green or black aphides may be destroyed by dusting them with tobacco powder. Where early Cucumbers and Melons are obtained from frames or pits heated by fermenting materials, some fresh Oak or Beech leaves should be thrown together, with one-third of stable litter, and if necessary be moistened so as to induce fermentation, and should be turned over so as to induce thorough incorporation of the materials.

Peaches and Nectarines.—Cease syringing the trees in the earliest house when the flowers show colour, maintaining, however, a moderate moisture in the house by damping the floor, &c., on bright mornings and in the early part of bright afternoons. The temperature may be maintained at 55° by day, ventilating freely from that degree upwards; close at 55°, 50° being sufficiently high for the night, and if the temperature fall to 45°, and in very sharp weather 40°, it will be more an advantage than otherwise. Examine the inside borders, and give if necessary a thorough supply of water at a temperature slightly in advance of that of the house. The trees for affording fruit fit for use at the close of May or early June should have their final dressing, be tied to the trellis, and the border inside be well watered. The house should then be closed, employing no fire heat except to exclude frost, damping the trees and house in the morning and early afternoon of bright days. Fire heat should not be applied by day to raise the temperature above 50°. The outside border should be protected with dry fern or litter, and if means are at command for throwing off heavy rains or snow it will be desirable to employ them. Push forward the pruning and dressing of trees in succession and late houses, carefully examining the inside borders, as dryness at the roots will cause the buds to fall later on.

PLANT HOUSES.

Greenhouse.—The earliest plants of herbaceous Calceolarias will require to be shifted into larger pots before they become rootbound. Calceolarias delight in a rich light soil, the following compost being well suited to their requirements:—Three parts fibrous loam, a fourth of leaf soil and well-decomposed manure, and a sixth of sand. The plants require a moist cool bottom to stand on, and plenty of air and light, with protection from frost. Show and Fancy varieties of Pelargoniums are very acceptable for conservatory decoration. Plants required to flower in May should now receive attention in staking. Vigorous young plants may have the points of the shoots pinched out; older plants that do not grow so vigorously will be better without stopping. The latest plants will now require potting. Fancy varieties should be similarly treated, placing them as near the glass as possible, keeping the temperature at about 40° at night and a few degrees higher by day, supplying no more water than is necessary to keep the soil a little moist, not, however, allowing the foliage to flag. In potting Pelargoniums care should be taken to ram the soil quite hard, light potting only encouraging leaf-growth. Be careful in watering Primulas, especially the double varieties, which are liable to damp off. Camellias swelling their flower buds may be assisted with weak liquid manure, especially weakly plants, and if the flowers are not opening freely afford a temperature of 50°.

Orchids.—Rest is of the greatest importance to Orchids than

Orchids.—Rest is of the greatest importance to Orchids, therefore be careful not to excite the plants into growth at this season. The temperature of the East India house should average 60° by day and 56° at night, Mexican house 55° by day and 60° at night, cool house 50° by day and 45° at night. Cool treatment at this season will induce a more vigorous growth subsequently. A very moist atmosphere at this season will cause serious injury; on the other hand, it should not be allowed to become too dry, or the stems and leaves will shrivel. Keep the glass clean, so that the plants have all the light possible. Plants of Dendrobium nobile that completed the growth early will have their flower buds in a forward state, and if placed in heat and supplied with a little water they will soon be in flower. By having plants in various stages a supply of flowers of this useful Orchid may be had from January to May. Plants for flowering at this last-named time should be placed in a greenhouse temperature and supplied with very little water until they begin to grow. Other Dendrobiums—such as D. densiflorum, D. Farmeri, and D. macrophyllum giganteum—not required to flower until May or June are easily kept back, they being now placed in a cool house and kept dry. It is very injurious to all plants, especially Orchids, to check the growth after it has once

started until it is completed. A good supply of sphagnum and peat should be placed under cover, spreading it on a damp floor.

TO CORRESPONDENTS.

FUCHSIAS PROSTED (Adam).—If when a portion of the bark is removed the wood is black the plants are probably killed, but if green they are alive. Yet even if they are killed above they may be alive below the soil, and in that case if cut down they will with good culture make fine flowering plasts next summer.

next summer.

GRAFTING VINES (Paddle).—We advise you to side-graft the Vines, affixing the scion to the main rod which is yet young. Obtain now a well-ripened scion at least 18 inches in length, and preserve it in moist soil in a cool place—out of doors will do—until the Vine in the house commences swelling its buds. Then take a slice from the middle of the scion 6 inches long and nearly down to the pith, also a corresponding slice from the stock for attaching the scion. Secure two together with matting, and bind with meas, which should be syringed occasionally. Insert the lower 6 inches of the scion in a common wine bottle, which keep filled with water, the top portion having one eye or bud protruding from the moss. This bud will grow almost as freely as if it were a portion of the Vine. The stock need not be out down, but the growth may be reduced in the summer as the graft extends. By this plan you ought to have a good cane the first esseon. Continue replenishing the water in the bottle until midsummer, or until the young rod reaches half way up the roof. Thanks for your letter about the Pear.

PLATTORRIUM ALCICORNE (Idem).—You may affix the plant to any flat piece of wood, but it would be better without bark, which is liable to decay and loosen the plants. It should be secured to the wood with copper wire and be syringed occasionally to encourage growth. The Seakale will answer admirably by the plan you propose, but light must be totally excluded. The Amaryllis bulbs may be nearly covered.

SHAILS (Sacri).—The mollesc you have sent is Limnea fossaria. |You have probably obtained the soil from near a ditch or stagmant water, and the "snails" you are now troubled with are hatched from eggs that have been deposited in the soil.

CONIFERS INJURED BY WIND (An Irish Suberriber) —We should not cut away the branches as you suggest so as to expose the stems, but should only shorten such that are greatly injured, and which prevent the growths above drooping, as they often will do, until they reach the ground. The thinner you make the shrubs at the base the more will the growth be injured by the wind. If you prune away all the lower branches we fear you will render the specimens more unsightly than they are now.

STOOKS FOR PAR TREES (A. D. S.).—As your soil is of a dry and easily nature the Pear would probably prove a better stock than the Quince; yet by making stations for the trees, by using stronger soil or even clay, and planting rather below than above the general level of the ground, and mulching the surface with manure, you may succeed with either the Pear or the Quince as a stock for the trees.

SEEDLING APPLE (T. B. Morton).—The seedling Apple is much like the Tulip Apple, but whether it is the same or not it is not worth preserving except for its high colour, which makes a good effect in the dessert.

LARGE GOOREBERRIES (Schoolmaster).—Red—London. Wonderful, Dan's Mistake and Conquering Hero. Yellow—Catherina, Drill, Leveller, and Peru. Green—Shiner, Thumper, Stockwell, and General. White—Antagonist, Careless, Snowdrift, and Freedom.

ASPIDISTRA LURIDA VARIEGATA (Doubtful, Brixton).—Although the plant will endure several degrees of frost as you have been informed, it is deserving of better care, as, when grown in a greenhouse, it forms one of the most useful plants in cultivation for the decoration of coridors and rooms. It is very largely grown on the continent, and is much appreciated for the adornment of hotels.

EARLY PEAS (Foung Gardener).—As you omitted sowing during the mild weather in early September, and require Peas as soon as possible, you help their sow seed of William I. in turves, in a frame or a light house, and keep them there until the weather enables you to plant them out. They must be kept cool and well ventilated to induce slow sturdy growth.

PLARTING RANUNCULUSES (Subscriber).—The soil should be retentive of moisture. The best kind is the virgin mould of some alluvial soil on the banks of the river or some lowland pasture. If the soil should be thought too poor a small addition of decayed cowdung will be advisable; but it must be so decomposed as to appear like a black powder. Let it be theroughly mixed with the soil whilst making the bed, in dry weather, about the month of September. Some time about the end of February or the first week in March, rake the surface of the bed in the morning of the day previous to that fixed upon for planting. Commence by drawing with a hoe adril across the end of the bed, 1½ inch deep; if deeper the roots will be weakeed the succeeding year, by forming a kind of stem nearer the surface; and if shallower, the plants are more liable to be struck with drought. The drill being drawn the right depth press each bulb or tuber slightly down into the ground; plant them, if large, 4 inches apart in the row; if small, \$\frac{1}{2}\$ inches will be a sufficient distance. Cover the crown of each tuber with fine sand. This will cause the tubers, when they are taken up in July, to come out of the ground quite clean for keeping. Then, with a short-tooked rake, draw the soil over the bulbs, and when it is level, with the head of the rake gently press the soil presty closely upon them.

EVERLASTINGS FOR CUTTING (Idem).—Of the numerous species and varieties suitable for the purpose you mention we select the following:—Hellchrysum monstrosum flore-pieno and its varieties album, roseum, and roccoccineum, purpureum, and luteum; Xeranthemum annuum flore-pieno and variety album; Acroclinium roseum and album; Ammobium alatum; Rhodanthe maculata, R. atrosanguinea, and R. Manglesii; Helipterum corymbi-florum; Waitzia corymbosa, W. grandiflora; Gomphrena globosa, and varieties alba, aurantiaca, carnea, purpurea, and striata; Statice Bonduelli, B. Thouinii, S. sinuata, and S. spicata. The Phloxes are not adapted to fearcing, but they might be retarded by adopting the treatment you describe.

VARIOUS (I. B.).—Case cannot be burned without sulphurous fumes being evolved, and these are injurious to plants. A boiler and pipes would be far more satisfactory for heating your Rose house than any gas stove that has come under our notice, but we have not seen the stove to which you refer. As the manure you mention has not been advertised we have no means of secretaining who are the vendors. We know of no Roses of the size you name; you may perhaps obtain the information you need by writing to the paper in which the sensational advertisement appeared. We know of no source near London for obtaining Briars except from nurserymen. Had you known as well as we do all the circumstances of the case in question, and the great distance involved, you would not have complained of the decision arrived at, and which was inevitable under the circumstances.

GRAFTED VIVES (J. A.).—Provided you have ample room for the growth of both rods without overcrowding the foliage both the varieties will succeed on the same stock. The Mill Hill Hamburgh will probably prove the more useful of the two, the Black Muscat of Alexandria, though a delictious Grape is rather liable to shank. Your other question shall be answered next week.

PRUNING VINES (Old Sub.).—If you will send us a lateral cut off close to the rod we can the better reply to your question on pruning; we will also at the same time reply to your Chrysanthemum question.

COMMERCIAL HORTICULTURE (J. R. J.).—There age not many firms which grow both fruit and flowers extensively for market, but Mr. Thomson of the Tweed Vineyards, Clovenfords, Galashiels, does. The following are a few of the principal growers of plants for the London market:—Messrs. J. & J. Hayes, Rdmonton; W. & A. Brown, Hendon; Hawkins & Bennett, Twickenham; Beewith & Son, Tottenham; Beeves, Acton; and Herbert, Richmond. Your friends had better visit those nurseries and make known their wants, and they will be certain to gather information that will be useful to them. Mr. Webber of the Central Avenue, Covent Garden, would be likely to inform you of the principal fruit-growing establishments near London.

HEATING ARRANGEMENTS (Light Brahma),—If you have two pipes from the feed cistern, one in connection with the flow and the other with the return pipes for heating the house, the water will circulate freely both in the pipes and cistern provided the arrangements are in other respects correct. By having valves in the pipes you can turn the heat on and off the house at will. You may force Rhubarb, Seakale, and Dwarf Kidney Beans in the house.

AN INDIAN PLANT (M. 8.).—From your description we think the plant referred to is Dischidia bengalensis, a native of India, and first received in Europe from the Calcutta Botanio Garden. The plant is parasitical in habit, succulent, and of a glaucous green colour. The stem is climbing, slender, and produces branching fibrous roots at intervals. The leaves are fleshy, elliptical, about 1½ inch long. The flowers are small, in axillary clusters, but are rarely produced in this country. It is related to Asciepias.

BUPHORBIA GUM (Bicycle).—We are unable to answer your question; perhaps you might obtain the information from a wholesale chemist.

NAMES OF FRUIT (Subscriber).—1, Susette de Bavay; 2, Verulam; 3, not known; 4, Glou Morçeau. (Comber).—2, Nouvean Poitean (small); 3, Glou Morçeau; 5, Martin Sec; 6, Not known.

NAMES OF PLANTS (J. Charteris).—1, Lomaria gibba; 3, Pteris serrulata cristata; 3, Asplenium obtusatum; 4, Onyohium japonioum; 2, Woodsia livensis; 6, appears to be a Lastrea, but the specimen was not bearing any spores. (J. Clarke).—Panicum plicatum. (F. James).—1, Agapanthus umbellatus variegatus; 2, Gasteria verruocea; 3, Begonia insignis; 4, Begonia metallica. (M.P.).—Crassula laotea. (An Inguirer).—Eupatorium riparium.

THE HOME FARM:

POULTRY, PIGEON, AND BEE CHRONICLE.

HOUSE AND SHED FEEDING OF SHEEP. (Continued from page 493.)

HAVING given in last week's Journal a sketch of the plans of house-feeding, &c., by Sir R. Simeon, the Rev. A. Huxtable, and Mr. Mechi, we must say that our proposal for earthing the pits is not only the best way to preserve the manure, but also to preserve the health of the animals, because the air mill be pure, and there will be no cold draught under the animals, the pits being partially or nearly filled with earth and manure, to be removed when inconveniently full. We will now proceed to give experiments relative to the advantages of house feeding compared with that of the open field, and also relating to the economy of the food consumed by the sheep during the period of fatting.

One of the first experiments as illustrating the advantage of shed feeding of sheep was carried out by the late Lord Ducis. One hundred sheep were placed in a shed, and ate 20 lbs. of Swedes each per day, whilst another hundred in the open air ate 25 lbs., and at the end of a certain period the former animals weighed \$ lbs. more than the latter. A still better illustration is given

by a Mr. Childers, as related by him in the Journal of the Royal Agricultural Society of England. A small yard was enclosed in the winter with post and rails, and a low thatched shed erected just large enough for twenty sheep to lie down in at once. The floor of this shed was boarded with rough slabs and raised 18 inches above the ground, and placed three-eighths of an inch apart, in order to allow a free passage of water and to keep the boards dry, as it was feared that the sheep might get the foot rot. On the 1st of January forty wether hogs were drawn out of his flock of Leicesters and divided into two equal lots, as near as they could be separated as to quality. On weighing each sheep the weight of one score was found to be 188 stone 8 lbs. and that of the other was 184 stone 4 lbs. The first lot was put into the yard with shed, and the other lot placed on turnips upon a field of dry sandy soil, well sheltered, and peculiarly favourable and healthy for sheep. Each lot received exactly the same quantity of food-viz., as many cut turnips as they could eat, which was about 27 stone per day, or nearly 19 lbs. each; 10 lbs. of linseed cake, at the rate of half a pound per sheep per day; half a pint of barley per sheep per day, a little hay, and a constant access to salt. For the first three weeks both lots consumed equal portions of food, but in the fourth week there was a falling-off in the consumption of the hogs in the shed of 8 stone of turnips per day, and in the ninth week there was a falling-off of 2 stone more; of linseed cake there was also a falling-off of 8 lbs. per day. The hogs in the field consumed the same quantity of food from first to last.

The result of the experiment was as follows:-From the 1st of January to the 1st of April the twenty shed hogs increased 56 stone 6 fbs., the twenty field hogs 36 stone 8 fbs., being per sheep 8 lbs. each per week for the former, and under 2 lbs. each per week for the latter-consequently, although the sheep in the shed consumed nearly one-fifth less food, yet they made above one-third greater progress. Now, this result shows the pecuniary advantage of attending to the comfort of sheep as well as other animals, the expediency of providing shelter when the weather is severe, and lessening their exercise. We shall quote one more experiment as carried out by a farmers' club some years ago, with the view of testing the feeding properties of different breeds of sheep fed under cover, the result being in favour of the Longwoolled Lincoln. The facts brought out, and the total result, are rather interesting and important to the home farmer. There were forty-two sheep altogether, each of which consumed on the average 26 lbs. of roots per day and rather more than half a pound of linseed cake. The average quantity of mutton made was 1 lb. 10 ozs. per week. We have other experiments which give as the result of consumption of 150 lbs. of turnips to make 1 lb. of mutton if fed in the open field, whereas when fed and housed in sheds under favourable circumstances 100 lbs. have succeeded in making the same quantity of mutton. This proportion of 150 lbs. of roots to 1 lb. of mutton being derived from numerous carefully conducted experiments made by different people is as near the fact as we are likely to arrive. It is somewhat important and interesting, because it may sometimes assist in estimating the feeding value of a given quantity of roots by taking the value of mutton per stone at the time, as it requires something like 1 ton of roots to make 14 lbs. of mutton.

A most important consideration arises after reflecting on the above results of feeding both under cover and in the field, whether shed feeding cannot be carried out in the open field. If this can be effected, and the manure left with tolerable regularity over the land, it must be of great consequence, for we acknowledge readily the great cost of carting the roots to the homestead, and afterwards carting the manure to the field. This matter has been tried in various ways; by erecting temporary shelter by thatched hurdles, and laying down straw for the animals to be upon—in fact, in severe weather we have known straw laid down without any shelter, and the sheep always are glad to resort to it to lie upon. But a very serious objection arises, the manure being left chiefly where the bedding was laid, and at the same time we have known it to increase the spread of lameness and foot rot; let us

therefore consider the advantage of a light iron shed upon a sledge or wheels, and therefore moveable daily, in order that the manure may be left with tolerable regularity. We will take 15 feet as the may be left with tolerable regularity. We will take 15 feet as the length, and from 10 to 12 feet as the width of the shed, with a ridged roof, closed on one side and both ends, with a sparred floor of wood, similar to that we have described for the floors in house or boxes. In such a case the manure, both liquid and solid, would or boxes. In such a case the manure, both liquid and solid, would pass through and manure the land with as much regularity as the removal of the shed will admit, the animals would be fed in troughs in the open, and only resort to the shed when the land was wet and the weather severe. Several sheds may be used at the same time if the number of sheep require it. We suggest this plan as the only one we can advise, having looked at the subject in every possible way. It only remains to be considered whether the house feeding or shed feeding in the field is the most economical. There are always so many circumstances to be considered that we will not now undertake to say which is not sidered that we will not now undertake to say which is most advantageous, as either plan may be useful under varying on-ditions. House feeding may be done with very little expense by the internal division of an old barn, and making a feeding path across each bay with iron hurdles, thus affording a large pen on either side of the path for the sheep to live and lie in, the floor of the barn being reserved for the store of hay, straw, and roots, and preparing the food. These pens for the sheep may be used by straw bedding, &c., as in shed feeding, or floored with spars for use without straw as before described. In the old barn the ventilation will be good as well as the shelter, and in foggy and close weather, the doors being left open, the accommodation would be perfect in all respects. By this means we obtain all the advantages required at the least expense, appropriating where possible old barns to accommodate cattle, sheep, horses, or swine, and we know of many such at present really preferable to buildand we know of many such at present really preferable to build-ings newly erected, and at a heavy cost. It will be readily seen by the home farmer how easy it will be to adapt or erect accom-modation for all animals which it may be desired by the pro-prietor to exhibit for prizes. Any kind of stock attended to properly in feeding, when carefully housed, will be sure to stand the best chance for reward on the day of exhibition; and we have referred to this matter most minutely owing to the great chies. referred to this matter most minutely, owing to the great objection made sometimes by gentlemen who do not entertain the question of exhibiting animals, because it takes the home farmer out of his usual course of management.

WORK ON THE HOME FARM.

Horse Labour.—This work has been greatly impeded lately in consequence of the frosty weather, the usual winter fallowing is therefore in arrears, and a considerable portion of wheat is still unsown. As soon as the weather proves open and mild wheat sowing will be resumed; and although it may be delayed, we ask the home farmer to disregard the observations of some who say the wheat should not be sown in the month of January. We say the wheat should not be sown in the month of January. We say from our experience drill the wheat after turnips fed off, or that might have been left oven a consequence of the lateness of the season, the first opportunity when the land can be worked easily and the land settles down closely around the plants more like it does in autumn-sown wheat. Should the drilling not be effected until February or March it is best to drill the wheat at 9 inches distance between the rows, in order that it may be hoed if occasion castance between the rows, in order that it may be need it occasion required, spring-sown wheat being more infested with weeds generally than that sown in autumn, and may therefore be heed with advantage, and clover seed heed in if it is intended to be followed with grass for hay. Various kinds of work also may be done whilst frost prevails, such as carting chalk from the pit or vessel, if obtained by water carriage, and laid out on the land at once. This is better than carting to a heap, as it saves the second carting and is more likely to meet with frost to reduce and separate the large lumps. Carting of dung and earth may now be done with large lumps. Carting of dung and earth may now be done with advantage, the latter especially; and the home farmer should at odd times all the year round be adding to the earth heap, extending it in one direction, and shortening the heap when it has been accumulated long enough to have become mellow and fit for use

in earthing the cattle pens, pigsties, &c.

Hand Labour.—This will now consist in attending the threshing Hand Labour.—This will now consist in attending the threshing machine, stacking the straw, &c.; and, in case the straw should be required for chaffing as cattle food, it should be spiced or flavoured at the time of ricking. In all the best corn-theshing machines it is turned out nicely winnowed, whether of wheat, barley, or cats. We have a new screen for separating the malting barley from the thin, which may be only fit for grinding, and it is of great importance to the home farmer to have his grains for different purposes separated at moderate cost. We have previously recommended a corn screen sold by Coleman & Morton, but we now advise the use of a screen exhibited at Islington Hall during the Cattle Show, called the Polygon Corn and Seed Screen. There are three numbers of them, adapted for various purposes, at a reasonable price. It is absolutely perfect in separating charlock and other weed seeds from wheat, barley, or cats; also will separate plantain seed from clover, stonewed from trefoil before being milled, and lastly it will separate barley from cats, which is a most important lastly it will separate barley from oats, which is a most important point, for when drege is grown upon mixed or heavy soil the

barley is invariably stouter than when grown alone. The screen is sold by Perkins, Paternoster, & Co., The Ironworks, Hitchin, Herts. The threshing of barley proves almost as bad in yield as wheat, and unfortunately the malsters complain that the barley, which in some few cases is plump in sample, will not sprout with regularity, and that they are therefore buying the foreign barley instead, the best we have seen being Danish produce, which they say works well. This is a serious matter, for if our own barley cannot be sold for malting it must be sold for 10s. per quarter less money, and for grinding purposes chiefly. This will also to some extent affect the value for seeding purposes next spring. Some farmers say that it will vegetate better if allowed to remain in stack for a few months; but we are not sure of this, as the barley did not ripen as usual. In feeding fatting cattle the roots will either be cut ripen as usual. In feeding fatting cattle the roots will either be cut or pulped. In either case the possibility of choking is removed, except when the slicer is used in outting, for larger pieces pass through the slicer than is possible when Gardner's cutter is used. There is, however, always some risk in feeding young stock or dairy cows with whole roots or cabbages with strong stumps, especially in frosty weather when the roots are partially frozen, for the cattle take them into their mouths, and in the endeavour to masticate the last piece it often slips over the root of the to maticate the last piece it often ships over the root of the tongue and is sometimes the cause of choking. The home farmer should therefore be prepared with the patent elastic probang, one end being globular with holes in to allow the air to pass into the tube in cases of hoven or blown, the other with a kind of cup to be introduced into the throat of the animal for the removal of be introduced into the throat of the animal for the removal of portions of roots which may obstruct the passage of the gullet. Sometimes, however, gruel given warm composed of oatmeal and a little oil will remove the obstruction, and this should be tried in ordinary cases before using the probang; but in case the obstruction is very serious, and the animals have great difficulty in breathing with extension of stomach like hoven, the probang should be used without delay. The Dorset down ewes will now be lambing, therefore the shepherd and under shepherd or assistant will both have full employment by night as well as by day, and where the lambing fold is not close to the shepherd's cottage a house upon wheels will be necessary, to afford the shepherd and his assistant shelter in bad weather, so that they may look to the swes by turns at night time. ewes by turns at night time.

THE POULTRY CLUB.

A COMMITTEE Meeting of the Poultry Club was held during A COMMITTEE Meeting of the Poultry Club was held during the Birmingham Show time: present, the Hon. and Rev. F. G. Dutton (President), the Hon. and Rev. A. Baillie-Hamilton, A. Darby, R. E. Horsfall, S. Matthew, Rev. J. D. Peake, E. Pritchard, Rev. W. Serjeantson, and O. E. Cresswell, Hon. Secretary.

The following new members were elected:—Rev. E. H. Morgan, Jesus Coll., Cambridge; E. W. Morris, jun., Cherwell Cottage, Widdington, Oxon; G. P. Pointer, 80, Goswell Road, Islington; Rev. E. C. Pritchard, Luton, Beds.

Various questions of private dispute were laid before the Club.

Various questions of private dispute were laid before the Club, but promptly settled in accordance with the resolutions of the Committee. Miss May Arnold had forwarded a statement concerning the two late contests of incubators at Hemel Hempstead. It was carefully considered, and it was resolved that Miss Arnold It was carefully considered, and it was resolved that Miss Arnold be requested to have in readiness evidence which she offered to supply, against further consideration of the matter, which was necessarily postponed, as Mr. Peel, Secretary of the said contests, is out of England. It was resolved that aid should be given by the Club to shows which accept its rules and apply for the same, and it was voted that six classes with prizes to the amount of £8 10s, in each should be guaranteed by the Club against loss at both the Shrewsbury and Wolverhampton Shows

STRAINS OF POULTRY.

CONTINUING our remarks from page 494, we advise every fancier who takes a pride in his or her birds, and who wishes to derive real pleasure from them, to set systematically to work to establish a real strain of a special breed. It may at first seem more attractive to keep three or four pens, each of a different variety, selected in a happy-go-lucky way. There certainly is much temptation to multiply our breeds, but if any permanent pleasure and real fame is desired it is far better to keep two or three pens of one kind, or in the case of those whose space and means allow it of two or three kinds, than to divide yards and interest among several sorts. If a beginner has a fancy for some particular breed, but is not sure what strain of that breed he prefers, he may wall have one non-free monatche. well have one pen from one stock and another from another, and observe the difference of the produce and retain whichever turns out best; every chicken must be carefully marked beyond possi-bility of mistake, or the experiment will be worse than useless and end in general confusion. It is very common for poultrymen to trust to remembering which chickens have come from a pen; this does very well up to a certain point, but then a time comes when they develope rapidly, the broods are broken up, and the sexes separated and then when distinction is really important

they can no longer be traced with certainty. This difficulty must be obviated by some indelible private mark. It is often a good plan, when a race is vigorous and is known not to have been closely inbred, to mate a peculiarly handsome bird directly with its parent. This may astonish some of our readers, and is directly contrary to the advice to be read in most poultry books; but we could quote many instances of its good result. We especially have in mind a splendid strain of Dark Brahmas thus begun; some characteristic beauty may thus be strongly stamped on a family, which may then be kept up for generations. Of course such a reunion must not be frequently resorted to, but through it probably first and second cousins will come of much the same type, and they again can be mated together for its perpetuation. It is well to note down to whom the best of our stock go. We have more than once refreshed our strains by buying some birds back of them for the sake of fresh blood, which course we much prefer

There are unfortunately some breeds of which it is almost absolutely necessary to keep up two strains if we desire to please the taste of the judges in both sexes. We have often inveighed against this system, and do not care now to return to the charge; suffice it to say that we believe it has done more to puzzle and disgust young fanciers than anything else. Even in the case of their breeds we fancy that careful selection and a gradual drawing together as it were of the two strains, may in time produce a race from which both sexes may be produced in excellence. We certainly have known this accomplished in a renowned yard of Dark Brahmas, and also to some extent in a not unsuccessful one of Golden-pencilled Hamburghs. The result of a systematic attempt to work up a strain is year by year seen more clearly, and cannot but be a source of much satisfaction to a genuine fancier; instead of a multitude of young birds of many types, few good sent, and it becomes unnecessary to breed a great number from which to select; this re-acts for the good of those which are reared, and gives them greater size and vigour; for this and quick development there is nothing like rearing poultry in small numbers. We shall be only too pleased if these very general hints about strains should induce some young fancier to set about working up any one breed to a high standard of ment, we are sure that his occupation may be made profitable as well as pleasurable.—C.

POULTRY REQUISITES.

Fowls require pure air, and plenty of it, at all times; therefore see that the hen houses are always clean and well ventilated. They should have fresh clean water daily, and never be allowed to go thirsty. Feed them regularly two or three times a day all they can eat up clean. Do not crowd your fowls in their quarters; give them as much room as possible to move about, and sufficient roosting accommodations. Subscribe for and read a poultry journal, follow out the advice and experience given in it by older breeders, and you cannot fail to succeed. There is very little, if any, hard work attached to it. It needs attention, however, and a share of good common sense, coupled with ordinary judgment in the manipulation, to produce and raise good fowls. You must be patient, and satisfied to reap your reward after the work is done, the same is at any other business. Do not be in haste to buy from the first man that you know has stock to sell. Ascertain who has good stock of the variety you intend to keep, pay a fair price for it, and you will be satisfied with the result. Begin aright, and continue to give the work a fair share daily of the necessary supervision that you would give to any other business from which you would expect to derive profit or excel in.—V.J. GIBSON (in American Pigeon and Poultry Bulletin.)

VARIETIES.

THE Exhibition of Canaries and British and Foreign Cage Birds which opens at the Alexandra Palace on January 26th, and continues for three days, will probably be a very large one. The schedule contains seventy-three classes, divided in four sections—viz., Canaries, British birds, Birds of Passage and Foreign birds. Three prizes are offered in each of the forty-five Canary classes, and two prizes in most of the other sections.

- —— At the Dorset County Poultry and Pigeon Show, which opens on January 14th in the Town Hall, Dorchester, we observe that ten silver cups and nine pieces of plate are, amongst other prizes, provided for competition. Amongst the donors are the President of the Show, Lord Allington; W. E. Brymer, Esq., M.P.; The Mayor of Dorchester, William Durdon, Esq.; Col. Denne and officers of the Royal Artillery; Captain Sutton, F. F. Sutton, and W. W. Turner, Esq., &c.
- Two correspondents, "J. D. W." and "R. J. S.," desire to know where Langshan fowls or their eggs can be obtained pure. Those having them should advertise, as there are no doubt several who would be glad to obtain this variety of fowl.
- AMERICAN AND CANADIAN FOOD.—During the whole of last week there was not a single head of either live cattle, sheep,

or pigs landed at Liverpool from the United States and Canada, a circumstance which has not occurred for many months past. The quantity of fresh beef brought during the same period was, however, large, and the arrivals of mutton, though not up to the previous week, were still above the average of recent weeks—namely, 6857 quarters of beef, 1444 carcases of mutton, and 103 dead pigs."

—— "THE Londoners," says the American Agriculturist, "will have a jolly good Christmas this year, for they have plenty of American beef and flour, Western turkeys, New York and New Hampshire apples, oysters and prairie chickens, besides Angelica wine from California. Little did Cornwallis anticipate such a state of things when he was surrendering Yorktown to Washington a hundred years ago."

——PROFESSOR SHELDON, in his work on dairy farming, assumes that 850,000,000 gallons of milk are annually made into cheese in England, and 550,000,000 gallons to butter. The quantity of the former product nade is 126,000 tons, and of the latter 89,285 tons.

- The very fact, says the Irish Farmers' Gazette, that the enormous sum of £8,000,000 is paid in one year for eggs and poultry, which are imported chiefly from France, and also from Canada and the States, and the high prices obtained for such articles, show that the home producer has a very ample field at command for extending his operations. The fact is, large farmers have hitherto regarded the production of poultry and eggs as a matter of minor importance which did not call for any special attention. It was tolerated, as it afforded a small supply of pocket money to "the mistress" and her daughters, which prevented the disagreeable necessity of extracting money from the parental purse when a fresh supply of ribbons or other essential accessories of female adornment were required. The poultry yard also afforded an agreeable variety in the ordinary dietary of the farmhouse; so that altogether it was a useful, if a minor, department of farmyard industry.
- THE AGRICULTURAL GAZETTE ALMANACK which we have received contains a great amount of valuable information of interest to the agricultural community. The special articles on several important subjects are admirably written; and the issue is embellished with portraits of notable agriculturists and machinists, the frontispiece appropriately containing a good likeness of the Duke of Bedford, the President of the Royal Agricultural Society. Some celebrated prize cattle are also represented by various engravings. It is an excellent publication of its kind.
- A CORRESPONDENT has sent us a peacock butterfly which he found during the recent cold weather flying about in his drawing-room. The occurrences of butterflies during the winter months in sitting-rooms may be thus explained. These insects that suddenly appear on the wing had entered the house some time in autumn while seeking a place to hybernate. Lodged there, perhaps amongst curtains or in some nook, they are roused from their retreats either by a noise or other disturbing cause, or by a higher temperature near their place of lodgment.
- Now that insect food is getting scarce we must, says the Prairie Farmer, provide our fowls with something in its place if we expect them to attend to laying duties. Those fortunate individuals who live near butchers can usually get all the meat they need for the fowls, but less favoured mortals are frequently put to their wit's end to provide a meal of meat for the biddies. If you have milk, sweet or sour, or buttermilk, give your fowls a pan of it every day, and they will need no meat. At hog-killing time save all the refuse scraps that usually go to the cats and dogs, salt them in an old keg, and you will have plenty of meat for your fowls. The best way to feed it is to freshen, boil until tender, chop fine and mix with soft feed, using the water that the meat was boiled in for mixing the mass. A little meat will go a good way—too much meat does more harm than good. A half pint of chopped meat is enough for a dozen fowls, and it should not be oftener than twice a week. It is more work to cook meat for fowls than it is to throw it to them raw in chunks, but the cooked food is the most economical, and if you expect to make poultry pay well you must study economy in everything.

BEES AND BEE-KEEPING.

BEE-KEEPING will never fail to be an interesting and pleasure-yielding pursuit, there being so many instructive facts connected with the habits and history of bees. It has always been surprising to me how easily bees find honey-bearing flowers, and how much they gather from them on the very first day of arrival in a strange place. The wonders of bee life are innumerable. Note two of them—first, the secretion of wax; second, the deposition and distribution of eggs. Wax is useful in domestic economy, and seems to be indispensable to men in various arts and sciences. It is a secretion of bees. Somebody has said that bees both "sow and reap," meaning thereby, I presume, that they fertilise flowers while gathering honey. But it is more correct to say that bees in making wax are both "servants and masters." They make their own bodies into wax manufactories when they need wax.

When wax is not required it is not made, the machinery of the factory is stopped. Where else in nature have we a marvel like factory is stopped. Where else in nature have we a marvel like this? Where else such economy as this voluntary cessation of a

natural secretion?

natural secretion?

Now for a word about the mysteries of the eggs of a queen bee. She produces what may be called male and female eggs; both it is believed are originally alike, but acted on differently in passing through the oviduct. The fertilised eggs are female in character, and the unfertilised eggs are male. The female eggs are laid in worker comb, or the smallest cells; the male eggs are laid in drone comb, which has larger cells. The reader may say, "There is nothing mysterious in all this." No, there is not much if it be admitted that the queen he has nower to determine any before admitted that the queen bee has power to determine sex before her eggs are laid, and also to discriminate and separate the male The possession of such power is very extraordinary, and perhaps is unparalleled in the whole range of nature. If the queen does not possess the power of determining sex and discriminating between fertilised and unfertilised eggs our difficulties are not lessened at all, the mystery is quite as great. The eggs are properly deposited, each sex in their proper places. Probably the separa-tion is made by some unexplained and unexplainable attribute of the queen by some unerring law or instinct beyond the ken of mortals. Two naturalists—viz., Professor Owen of England and Professor Siebold of Germany, have very carefully examined under the microscope fresh-laid eggs, and found traces of a difference between those that are female and those that are not. Some years ago I took some drone eggs (a piece of drone comb containyears ago 1 took some drone eggs (a piece of drone comb containing eggs) from a hive, and gave them to another hive without a queen. The bees most gladly accepted the eggs, and at once began to erect royal cells around five of them. The eggs became maggots and were sealed over at the proper time. Evidently the bees were satisfied, and expected queens to issue from these cells, but their hopes were blighted. On or about the sixteenth day after the eggs were received and adopted the royal cells were cut out and opened. The graphs were all dead 1 was then convinced out and opened. The grubs were all dead. I was then convinced of two things—that eggs are of a fixed sex, either male or female, and that the working bees do not know the one from the other. In this experiment the treatment given was improper and killed the grubs. It is not at all unlikely that deeper researches and the grubs. It is not at all unlikely that deeper researches and fresh discoveries will be made in bee-history, and cause additional interest to be taken in our little favourites. "Every day it may interest to be taken in our little favourites. "Every day it may be said that old and apparently established theories fade away and give place to others very different; indeed, it may be said that we are still engaged in studying the introduction to the natural history of bees."

Those who have studied the honey bee anatomically and micro-

scopically tell us that it is a wonderful creature in its structure scopically tell us that it is a wonderful creature in its structure and mechanism—that externally and internally it is beautiful and complicated, presenting striking features that are admirably adapted to its habits of life. It has many handy instruments about the mouth—toothed shears for clipping and gnawing wax and propolis; trowel-mouthed blades for plastering and moulding; a long narrow tongue, which serves in the building of the cell walls. A bee has six legs, five joints to a leg; and its legs are used for more purposes than locomotion. It has baskets on its hind legs for pollen, and forked claws at their points—useful in domestic work and for holding by. The antennes or feelers of in domestic work and for holding by. The antennæ or feelers of the bee have thirteen joints, and are wonderful and useful organs. It has been fancied by some that the antenne of bees perform the functions of hearing, smelling, and feeling; but this is an unsettled question. That the antennes are organs of feeling is evident. When bees are deprived of them they seem to become quite imbedie. The eye of a bee is said to contain above three quite imbecile. The eye of a bee is said to contain above three thousand small but perfect hexagonal lenses, and is considered one of the most exquisitely constructed optical instruments in The wings of the bee are strong and tough, four in number, two larger and two smaller; and what is remarkable is the fact that two wings on each side of the bee can be hooked together fact that two wings on each side of the bee can be hooked together and work jointly as an unbroken surface or fan. On the edge of one wing there is a rim or bar, and opposite, on the edge of the other wing, there is a row of hooks, which when connected lock the two wings together, and when thus used in fanning the hive they vibrate rapidly and create a strong current of air. In condensing and presenting these thoughts on the anatomy of the honey bee from the works of writers on the subject I have left but little space for remarks on bee-keeping. Profit-and-loss halances in bee-keeping are the paramount consideration with

balances in bee-keeping are the paramount consideration with me. The year now near its close has been one of great depres-sion and loss; dull trade from beginning to end, bankruptcies and liquidations everywhere—the worst year for bees I have ever known. 1886 and 1861 were bad enough, but I think 1879 was worse. One thing can be said in favour of 1879—it was no respector of districts, but affected England, Ireland, and Scotland like. All anising falls and suffered from the unfavourable alike. All apiarians felt and suffered from the unfavourable season. But practical and experienced bee-keepers are not easily discouraged. They look hopefully forward, and ever find themselves more engaged with the future than the past. Hives may be rather weak in spring. The queens in some hives will be a year too old. Nursing and care will be required, but now-a-days

apiarians have knowledge and cultural skill. Some ten years ago apiatrams have knowledge and cultural skill. Some ten years ago it was hardly possible to find a person in England with an intelligent and comprehensive knowledge of bee-keeping; now we have thousands of apiarians who possess a knowledge of the principles of theoretical and practical management of bees, and many of them are able teachers, and act as such in their neighbourhoods.

The motto given to bee-keepers for the last two years was "Onwards—excel," for next year it is "Never despair." Bee-keepers who have had their stocks reduced in number or lessened in who have a should commence again and look hopefully forward. We have fifty stocks, and have as much confidence in them and

the future as anybody ever had.

In wishing all apiarians a happy and successful new year, let me suggest the importance of aiming at excellence—pursuing an independent course of management, remembering that those who follow are always behind. It is well known that novelty has charms to the young and inexperienced, but all should remember that new ideas in science and practice cannot be properly valued until time has sobered the enthusiasm of their advocates.— A. PETTIGREW.

THE SWISS HONEY-CAKE.

IN Switzerland and Italy a peculiar kind of honey-cake is always found on the dessert plates of every table d'hôte—i.e., the dinner table where a regular course is served up at a stipulated price to all guests alike. The Continental Gazette of August 28th gives the following description of this honey-cake, or "Leckerli," as it is called :-

Every tourist in Switzerland quickly becomes acquainted with the oblong little biscuit compounded of honey, flour, and certain roots, which goes by the name of "Basler Leckerlı." He sees it invariably on the dessert plates at every table d'hôte; the waiters of the Basle hotels are almost certain to thrust a packet of it upon his notice before he leaves the city; on his way to Basle or on his way from it, at the buffets of nearly every railway station in Alsace and Baden, he will be confronted by a small glass case with the superscription "Basler Leckerli," or the French adaptawith the superscription "Basler Leckerli," or the French adaptation, "Leckerlis de Bâle." He may or may not be pleased with the curious flavour of this widely-advertised delicacy of the local confectioners, which is as famous in Basle as the "Lebkerchen" in Nuremberg and Berne, or the "Spanish bread" in Baden. Here and there in the streets of Basle he will come upon a manufactory of the article—"Leckerli-fabrik"—the sight of which will the base of the sources considered the second factory of the article—"Leckerli-fabrik"—the sight of which will give him some conception of the enormous quantities of this piece of confectionery which are produced in the town of Holbein and Erasmus. A Swiss "Cook's Lexicone" gives no fewer than fifteen recipes for the concoction of Leckerli, and the popular dialectic poet of Basle, Theodor Meyer Merian, has devoted an entire poem to its history, qualities, and uses. The greatest trade in it, however, is done during the Christmas season. Thousands and thousands of packets are then sent by the Swiss to their friends and to children through the poet; and it is said that a Switzer never goes to Basle on a tour of business or pleasure without being strictly charged by his wife and children, "Be sure to bring back a packet of real Leckerli."

METROROLOGICAL OBSERVATIONS.

In consequence of our going to press earlier than usual this week the publication of the meteorological observations must be postponed until our

COVERT GARDEN MARKET .- DECEMBER 94.
